ABSTRACT

Optimally scheduling a team of developers on a large software project is an NP-complete problem. The scheduling algorithm employed by the Evolutionary Control System (ECS) portion of the Computer-Aided Prototyping System (CAPS) does near-optimal scheduling using an algorithm that runs in Order N^2 space and time. The problem addressed by this thesis is to improve the performance of the algorithm and make it more useful for scheduling software developers. The thesis accomplished three things: (1) Modified the algorithm to run in order N time and space, preserving its near-optimal behavior; (2) implemented a calendaring package that computes federal holidays for any year after 1970 and schedules tasks only on non-holiday workdays; and (3) incorporated a more realistic capability model to better match programming tasks with each developer's abilities.

ACKNOWLEDGMENTS

Thanks to Professors Berzins and Luqi for their time, and kind solicitude. It is an honor to have been a student of theirs. Thanks to the enlightened management of NRaD for setting up the distance-learning program, thus giving my classmates and I the opportunity to earn an advanced degree from the Naval Postgraduate School. And last, thanks to my family for allowing me to take from them the hundreds of evenings and countless weekends necessary to complete this program. My debt to them is immeasurable.

I. BACKGROUND

Much research into the formalization and automation of software development is underway. The need for such tools is obvious. It is fundamentally driven by Moore's Law, which states that the power of computer systems will double every 18 months—a maxim which has held for the past twenty years, and is expected to continue for at least the next ten. As computer systems grow inexorably faster and more powerful, new software to take advantage of this increased power is needed. The new software, however, is larger, and more complicated, and now requires larger teams of developers to produce in a timely manner. Software tools to manage the complexity of developing these larger programs are needed.

One such tool is the Evolutionary Control System (ECS) being developed at the Naval Postgraduate School (NPS). The basis of the ECS is Salah Badr's Phd. Thesis, *A Model and Algorithms for a Software Evolution Control System*[Ref. 1], which itself was based on work by Luqi[Ref. 4] of NPS.

Salah's thesis delved into a broad array of issues related to managing large projects and their concomitant complexity. One aspect of his thesis, which is the subject of this report, was the development and implementation of an on-line scheduling algorithm that did three specific tasks:

1. Supported teamwork by concurrently assigning ready steps to available designers.
2. Supported incremental replanning as additional information became available.
3. Minimized wasted design effort due to reorganization of the schedule by efficiently scheduling workers to assigned sub-tasks.

Over time, however, certain limitations have become evident. The implementation of the scheduling algorithm was found to be $O(N^2)$ in space. This led to a rapid exhaustion of memory resources on relatively small problem sets. Also, the model of time used to schedule the developers was not realistic. It assumed that the

developers were available always, and did not take into account weekends, holidays, or other commitments on a developer's time. Also, the capabilities of the developers was split into just three broad categories: low, medium, and high. This too proved unrealistic, as certain developers bring their own strengths and weaknesses to the task at hand. It would be nice to take note, for instance, of a special ability such as database expertise, and assign a programmer with this capability to a task that require this knowledge. The changes made to Salah Badr's codes do exactly this.

II. THE SCHEDULER

The problem of optimally scheduling tasks for both the preemptive and nonpreemptive cases is NP-complete[Ref. 6]. Scheduling nonpreemptive tasks with arbitrary ready times is also NP-complete in both multiprocessor and uniprocessor systems[Ref. 3]. For dynamic systems with more than one task, and mutual exclusion constraints between tasks, Mok and Dertouzos[Ref. 5] showed that an optimal scheduling algorithm does not exist.

Shiah, et al.[Ref. 2] came up with an heuristic scheduling algorithm that ran in order kN time. Salah Badr extended the algorithm to consider arbitrary precedence constraints between pairs of tasks. His scheduler forms the basis of the current ECS scheduling algorithm.

The scheduling algorithm, as implemented by Badr, was recursive. It consumed order N^2 memory for a set of N tasks. It attempted to improve performance by limiting backtracking, but was still at least order N^2 in time. It was based on an algorithm described in the paper by Stankovic, et al.[Ref. 3] The requirement for order N^2 space limited the size of the problem domain. This thesis describes the algorithm and the steps taken to make the algorithm run using only order N space. It is based on the "myopic" algorithm[Ref. 2] and a radical restructuring of the data structures in the Ada code.

A. THE SCHEDULING MODEL

The task set in the ECS scheduling problem is a variable set of evolution steps $S = \{S_1, S_2, \dots, S_N\}$, where N varies with time. This set of tasks needs to be scheduled to a set of M designers $D = \{D_1, D_2, \dots, D_M\}$. The designers are of L different expertise levels.

Tasks as used in the ECS are independent, nonperiodic and non-preemptive. They can be characterized by the following:

1. Task arrival Time T_A ;
2. Task deadline T_D ;
3. Task worst-case computation time T_C ;
4. Task expertise level T_L ;
5. Task priority T_P

Each task also has associated with it a precedence constraint given in the form of a directed acyclic graph $G = \{S, E\}$ such that $(S_i, S_j) \in E$ implies that S_j cannot start until S_i has completed.

The priority, T_P , is a small positive integer that is assigned to each task to reflect the criticality of its deadline. The priorities of different tasks should be compatible with the precedence constraints between the steps, i.e. no lower priority step can precede a higher priority step:

$$\begin{aligned} &\text{if } (S_2, S_1) \in E \Rightarrow T_P(2) \geq T_P(1) \\ &\text{if } (S_2, S_1) \in E \wedge T_P(1) \geq T_P(3) \Rightarrow T_P(2) \geq T_P(3) \end{aligned}$$

B. THE SCHEDULING ALGORITHM

The goal of the scheduling algorithm is to determine if there exists a schedule for executing the tasks that satisfies the timing, precedence, and resource constraints, and to calculate such a schedule if it exists. A schedule that meets these constraints is termed *feasible*. It is not guaranteed to be optimal.

Scheduling a set of tasks to find a full feasible schedule is actually a search problem. The search space is a tree. The scheduling algorithm starts at the root of the tree, and using a predetermined heuristic, selects a candidate task to schedule. If the remaining tasks can be added to the schedule, in the order given by the heuristic, without violating the constraints, then the partial schedule is termed *strongly-feasible*, and the task is added to the search tree as a vertex node, and the process is repeated, recursively, till a full, feasible schedule is found. If instead, after the candidate task is

selected, and any one of the remaining tasks added to the schedule violates the constraints, the candidate task is rejected, and the next eligible, candidate task (ordered by the ranking function $H(T)$) is selected. The search process continues until all the tasks are scheduled, or no feasible schedule is found.

Instead of using all of the remaining tasks to determine if a partial schedule is *strongly-feasible*, Stankovic, et al.[Ref. 2], limited the candidate tasks to check to some number k . So, instead of checking $N, N - 1, \dots, 1$ remaining tasks, or $N(N - 1)/2$ total tasks, they limited the search to k or at most kN tasks to check. (This is where the term "myopic" comes in. Instead of looking at all the remaining tasks, we "near-sightedly" examine the next k tasks.)

The set of tasks ready to be scheduled are ordered by the heuristic $H(T)$. The candidate heuristics are

1. Minimum deadline first (Min_D): $H(T) = T_D$;
2. Minimum processing time first (Min_P): $H(T) = T_P$;
3. Minimum earliest start time first (Min_S): $H(T) = T_{est}$;
4. Minimum laxity first (Min_L): $H(T) = T_D - (T_{est} + T_P)$;
5. Min_D + Min_P: $H(T) = T_D + W \times T_P$;
6. Min_D + Min_S: $H(T) = T_D + W \times T_{est}$;

According to Shiah et al.[Ref. 3], The Min_D + Min_S heuristic is superior in all cases. It is supposedly used in Salah Badr's dissertation, but since his simulation studies apparently used tasks with an earliest start time of 0 it defaults to Min_D. Min_D is used in the new implementation of the scheduling algorithm.

C. ANALYSIS

The scheduler as implemented by Salah Badr in Ada was Order N-squared in space. The heart of the code was a call on a search function performing a recursive search in tree-like fashion of potential schedules. In order to make the routine

Figure 1. Plot of scheduler run-time vs. number of tasks to schedule

$O(N)$ in space it was necessary to pull many of the large data structures out of the recursive routine, make them global, and manage changes with other global data structures. This necessarily complicated the code to a degree, but the result was an $O(N)$ algorithm in space.

Once the space problem was corrected, it became evident that the routine was also $O(N^2)$ in time. But this was easily rectified by using the “myopic” algorithm. Figure 1 shows the speed-up in processing speed vs. number of tasks to be scheduled for different versions of the code. The original data came with the original code. After the N^2 space problem was resolved, and before the myopic version of the code was added (first cut) we see that the code still runs in order N^2 time. The final cut shows the run-time for the final version of the code.

The original data collected goes upto only 4600 tasks because the storage required was $O(N^2)$ in the number of tasks to be scheduled. A number larger than 4600 tasks would cause the program to raise a storage-error exception.

Figure 2. Plot of Laxity vs. percent schedules found

D. SIMULATION

To test the new scheduler routine, a routine to generate tasks that always have a feasible schedule was written. (Actually Badr had a routine to generate tasks, but it generated lists of tasks that were “easy” to schedule—that is the algorithm never failed to find a schedule.) This routine varies the number of tasks, the number of programmers to use, and the “laxity” of the schedule generated. (Laxity is defined to be $T_D - (T_{est} + T_P)$.) It also uses the Ada '95 random number generators to generate uniform distributions of random variables. The graph in Figure 2 shows the performance of the algorithm when 500 tasks per test case were generated, and the laxity was varied between zero and 0.7. As you can see, the algorithm failed miserably when there was zero laxity, and got progressively better as this constraint was “relaxed.”

III. CALENDAR

The scheduling algorithm as originally implemented treated time continuously. Mapping this "continuous" time to calendar working time is a tedious task, especially as the number of tasks to schedule increases. Also, real dates give a better idea of the time-frames involved.

The algorithm to translate a "continuous" time to calendar time works as follows: Consider the output of the scheduler in Table I for a simple set of 10 tasks.

The first column is the task id, the second column is the expertise level required for the task (more on expertise levels, later), and the third column is the developer assigned to the task. (In this case we have three developers: L1, M1, H1.) The second to last column is the start time and the last column is the end time in units of hours.

After translating the start times and end times to calendar times we get the output in Table II For this data set the start date was set to July 3rd, 1997. The translator also assumed that the work day is eight hours. At NRaD the the work weeks are 5/4, i.e., 9 hours a day on Monday thru Thursday and 8 hours on Friday, with every other Friday off. Using -nrad as an input switch to the program, we get the new output shown in Table III.

The dates in Table III start on the seventh of July because July 4th is a federal

Table III. NRaD Schedule

holiday, and an NRaD off-Friday, this moves the off-Friday to the 3rd, so the first work-day is actually the seventh. It appears complicated, but the Ada implementation handles it quite easily. The format of MM/DD/YYYY+HR is used because daily schedules are idiosyncratic. The notation "+HH" means start or finish at that many hours into the workday. It should be easy to map this time format to any person's particular schedule, but in the interest of time was not done here.

The calendar package will also compute non-federal holidays such as Easter, election-day, and other useful dates. The present version runs in order N^2 time. It should be easy to convert to order N , but due to time constraints, this was not done during the course of this thesis. The calendar package was originally added to the

scheduler, but it didn't make sense to take an order N^2 algorithm, turn it into an order N one, then turn it back to an order N^2 one with the addition of the calendar package. Besides, the scheduler is used to come up with feasible schedules. Once one is obtained, it can then be easily mapped to calendar dates. This separation of tasks also preserves the modularity of the codes. The conversion routine to convert from "continuous-time" to calendar dates (*contocal*) is in one of the appendices, as part of the scheduler package.

IV. EXPERTISE LEVELS

Every programmer brings certain competencies to the tasks at hand. Some are experts in Ada, others in Java, etc. So, the scheduler has been modified to handle this.

In the Shiah, et al. paper[Ref. 3] on scheduling multiple tasks, resources are represented by a vector data structure as follows:

$$EAT = (EAT_1, EAT_2, \dots, EAT_r)$$

(EAT stands for earliest available time.) If a task is ready to be scheduled, and it requires resource N , the earliest it can be scheduled is at time EAT_N . If there are multiple instances of a resource then the resources are represented as a matrix, and the earliest time a task can be scheduled is the earliest time any one of the multiple instances of that resource is available. In Salah Badr's thesis, he represented developers as the resources, and since he classified them as (*low, medium, high*) he could have multiple instances of developers. So the data structure to represent the available resources (developers) was a matrix.

In this latest revision of the code, each developer is unique, there are no multiple instances of a developer, so resources (developers) are represented as a vector. Each developer, though, has a capability attribute, which is a map of skills to (*low, medium, high*). For example, one of the inputs to the new scheduler program is a file of developers, as shown in Table IV.

Each developer has an implicit attribute which is their name. Also, if a capability is not given, it is assumed to be *low*. For example developer "Scott McNealy"

Bill Gates	{ActiveX : High, Java : Low}
Scott McNealy	{Java : High, Unix : Medium}
Bill Joy	{Java : High, Unix : High}

Table IV. Sample developer file

Bill Gates	{ActiveX : High, Java : Low, Unix : Low, Bill Gates : High, Scott McNealy : Low, Bill Joy : Low}
Scott McNealy	{ActiveX : Low, Java : High, Unix : Medium, Bill Gates : Low, Scott McNealy : High, Bill Joy : Low}
Bill Joy	{ActiveX : Low, Java : High, Unix : High, Bill Gates : Low, Scott McNealy : Low, Bill Joy : High}

Table V. Sample developer file with implicit capabilities

is assumed to have *low* ActiveX skills, while developer "Bill Gates" is assumed to have *low* Unix skills. If a task is to be scheduled that requires *medium* Unix skills and low ActiveX skills then either developer "Scott McNealy" or "Bill Joy" could be assigned. On the other hand, if a task requires *high* ActiveX skills, then only "Bill Gates" would fit the bill. If a task came in that required *high* skills in both ActiveX and Java, no developer would fit the bill, and the scheduler code would through an Ada (noqualifieddevelopers) exception. If a job came in that required *high* or *medium* skills in attribute "Scott McNealy" then only he could possibly be assigned this job. Table V shows what the capabilities of each developer are with the implicit capabilities added.

V. CONCLUSIONS

A. SUMMARY OF DESIGN AND IMPLEMENTATION

The scheduler as implemented can now handle large problems in a reasonable time, i.e., ten thousand or more tasks. The scheduled tasks can now be mapped to a realistic calendar, and the tasks are now associated with problem-solving skills

B. FUTURE WORK

The calendar implementation needs to be optimized. It currently runs in order N^2 time, but could easily be modified to run in order N time. At present the calendar model does not consider individual variations in schedules. If a developer were to take a day off, the model cannot handle that, as it is only aware of work days and holidays for the general work-force. To allow individual schedules into the model a group planning program of some kind would be needed. A kludge to get around this in the present implementation, is to create pseudo-tasks lasting the period of time off, and requiring only that particular developer perform it. This causes some inaccuracies because the current scheduler is non-preemptive, but in real life time off could be scheduled in the middle of a task. This weakens the algorithm because it can fail to find feasible schedules in which tasks are interrupted by time off.

Another enhancement that would be useful is the identification of critical paths. All schedules have critical paths, that is a sequence of tasks with the least laxity. It would be nice to enhance the scheduler to identify these critical paths. The project manager could then focus his attention on those tasks in the critical path, as these would be the jobs that put his schedule most at risk.

WEB OUTPUT

APPENDIX A §

This page intentionally left blank

1. **Introduction.** Here is the Ada code for utilities used in Salah Badr's scheduler program. His program was written by him May 25, 1993. It was translated by myself, John Evans of NRaD, into Donald Knuth's WEB format for literate programming. To compile and link the code in its present format you will need the Ada version of the WEB tool.

It is available on-line via the world-wide-web at URL:

<http://white.nosc.mil/~evansjr/literate/>

2. WEB is a literate programming paradigm for C, Pascal or Ada, and other languages. This style of programming is called "Literate Programming." For Further information get the book *Literate Programming*, by Donald Knuth, published by the Center for the Study of Language and Information, Stanford University, 1992. Another good source of information is the Usenet group *comp.programming.literate*. It has information on tools and answers to Frequently Asked Questions (FAQs).

3. Who should use the WEB paradigm for programming? Well, not everybody. Here are a few paragraphs from Donald Knuth's book that explains it best.

4. **Retrospect and Prospects.** Enthusiastic reports about new computer languages, by the authors of those languages, are commonplace. Hence I'm well aware of the fact that my own experiences cannot be extrapolated too far. I also realize that, whenever I have encountered a problem with WEB, I've simply changed the system; other users of WEB cannot operate under the same ground rules.

5. However, I believe that I have stumbled on a way of programming that produces better programs that are more portable and more easily understood and maintained than ever before; furthermore, the system seems to work with large programs as well as with small ones. I'm pleased that my work on typography, which began as an application of computers to another field, has come full circle and become an application of typography to the heart of computer science; I like to think of WEB as a neat "spinoff" of my research on T_EX. However, all of my experiences with this system have been highly colored by my own tastes, and only time will tell if a large number of other people will find WEB to be equally attractive and useful.

6. I made a conscious decision not to design a language that would be suitable for everybody. My goal was to provide a tool for system programmers, not for high school students or for hobbyists. I don't have anything against high school students and hobbyists, but I don't believe every computer language should attempt to offer all things to all people. A user of WEB needs to be good enough at computer science that he or she is comfortable dealing with several languages simultaneously. Since WEB combines TeX and Pascal with a few rules of its own, WEB programs can contain WEB syntax errors. TeX syntax errors, Pascal syntax errors, and algorithmic errors; in practice, all four types of errors occur, and a bit of sophistication is needed to sort out which is which. Computer specialists tend to be better at such things than other people. I have found that WEB programs can be debugged rapidly in spite of the profusion of languages, but I'm sure that many other intelligent people will find such a task difficult.
7. In other words, WEB seems to be specifically for the peculiar breed of people who are called computer scientists. And I'm pretty sure that there are also a lot of computer scientists who will not enjoy using WEB; some of us are glad that traditional programming languages have comparatively primitive capabilities for inserted comments, because such difficulties provide a good excuse for not documenting programs well. Thus, WEB may be only for the subset of computer scientists who like to write and to explain what they are doing. My hope is that the ability to make explanations more natural will cause more programmers to discover the joys of literate programming, because I believe it's quite a pleasure to combine verbal and mathematical skills; but perhaps I'm hoping for too much. The fact that at least one paper has been written that is a syntactically correct ALGOL 68 program encourages me to persevere in my hopes for the future. Perhaps we will even one day find Pulitzer prizes awarded to computer programs.
8. Donald Knuth goes on to write about his hopes for the future of WEB programming. In an interview with Donald Knuth by Amazon Books on the release of a new edition of Volume 1 of *The Art of Computer Programming* (July 1, 1997) he was asked:
Amazon.com: What do you see as the most interesting advance in programming since you published the first edition?
Donald Knuth: It's what I call literate programming, a technique for writing, documenting, and maintaining programs using a high-level language combined with a written language like English. This is discussed in my book *Literate Programming*.
9. In the same book, *Literate Programming*, there is a chapter called *How to read a WEB*. But it is actually quite straightforward.

10. Very briefly, each “Module” within angle brackets (< >) is expanded somewhere further down in the document. The trailing number you see within the brackets is where you can find this expansion. This provides a type of PDL (program descriptor language) for your program and greatly aids modularity and readability. It is also a highly effective method of top-down programming. The first module here is expanded further down, and contains most of the structure in standard Ada packages.

⟨Package boiler-plate 12⟩

11. Schedule Tools.

12. Here, finally, is the boilerplate. The Ada WEB tool *atangle* reads this and knows to write out two separate files, the specification and the body. (The Ada WEB tool *aweave* will write out just one documentation file.)

```

```

This code is used in section 10.

13. The scheduling tools in this package rely on some other packages. Here is how they relate to each other.

Library Dependence Structure.

14. The schedules are kept in in linked-lists. Salah Badr's original code had separate routines for each linked list. In this version of the algorithm, I created a generic list type, and make multiple instantiations of it for different record types. Details of the differing records, comparisons, and display routines can be found in the `schedprims` package.

15. Since the main purpose of rewriting the code was to eliminate the order N^2 space requirement, I use linked lists to keep track of additions and deletions to the lists as the search space is traversed. What follows are all the instantiations of new linked-lists.

16. Here I instantiate a list type to manipulate *StepRecord* types.

`(Instantiate generics 16) ≡`

```

package InputList1 is new Generic_list(ElementType ⇒ StepRecord,
    DisplayElement ⇒ DisplayStepRecord, "<" ⇒ CompareID);
use InputList1;
subtype InputList is InputList1.List;
  
```

See also sections 17, 18, 19, 20, 21, and 22.

This code is used in section 12.

17. Here I instantiate a list type to manipulate *StepRecord* types, but to restore deletions, in case the recursive procedure *BranchAndBound* needs to back out changes.

`(Instantiate generics 16) +≡`

```

package DeletedInputList1 is new Generic_list(ElementType ⇒ StepRecord,
    DisplayElement ⇒ DisplayStepRecord, "<" ⇒ CompareRecursionLevel);
use DeletedInputList1;
subtype DeletedInputList is DeletedInputList1.List;
  
```

18. Here I instantiate a list type to manipulate *StepRecord* types for the *ReadyQueue*, which requires that the records be sorted in *Deadline* first order.

```
(Instantiate generics 16) +≡
package ReadyList1 is new Generic_list(ElementType ⇒ StepRecord,
    DisplayElement ⇒ DisplayStepRecord, "<" ⇒ CompareDeadline, "=" ⇒ IsEqual);
use ReadyList1;
subtype ReadyList is ReadyList1.List;
```

19. Here I instantiate a list type to manipulate *StepRecord* types for deletions to the *ReadyQueue*, which requires that the records be sorted in *RecursionLevel* first order.

```
(Instantiate generics 16) +≡
package DeletedReadyList1 is new Generic_list(ElementType ⇒ StepRecord,
    DisplayElement ⇒ DisplayStepRecord, "<" ⇒ CompareRecursionLevel);
use DeletedReadyList1;
subtype DeletedReadyList is DeletedReadyList1.List;
```

20. Here I instantiate a list type to manipulate *StepRecord* types for additions to the *ReadyQueue*, which requires that the records be sorted in *RecursionLevel* first order.

```
(Instantiate generics 16) +≡
package AddedReadyList1 is new Generic_list(ElementType ⇒ StepRecord,
    DisplayElement ⇒ DisplayStepRecord, "<" ⇒ CompareRecursionLevel);
use AddedReadyList1;
subtype AddedReadyList is AddedReadyList1.List;
```

21. Here I instantiate a list type to manipulate *StepRecord* types for the *ReadyQueue*, which requires that the records be sorted in *Deadline* first order.

```
(Instantiate generics 16) +≡
package ScheduleList1 is new Generic_list(ElementType ⇒ ScheduleRecord,
    DisplayElement ⇒ DisplayScheduleRecord, "<" ⇒ CompareStartTime);
use ScheduleList1;
subtype ScheduleList is ScheduleList1.List;
```

22. Here I instantiate a list type to manipulate *StepRecord* types for the *ReadyQueue*, which requires that the records be sorted in *Deadline* first order.

```
(Instantiate generics 16) +≡
package CalendarList1 is new Generic_list(ElementType ⇒ CalendarRecord,
    DisplayElement ⇒ DisplayCalendarRecord, "<" ⇒ CompareStartTime);
use CalendarList1;
subtype CalendarList is CalendarList1.List;
```

recursion_level : *natural* ← 0;

See also sections 24, 25, 33, and 59.

This code is used in section 12.

24. When the laxity of the input schedule is “tight,” it may be impossible to find a schedule. (Finding a schedule is, after all, an NP-Complete problem.) In this case the routine will give up after some amount of effort. In this implementation, I give up if the number of “backtracks” is *FeasFactor* times the total of number of tasks to be scheduled. If this number is exceeded then the exception *NoFeasibleScheduleFound* is thrown.

CHECK IN DEGREE

APPENDIX A §60

60. Check In Degree. Checking the *in_degree* of the successors of the assigned step. This works with deadline heuristic

61. Presently changes the start-time of any successors. Will need to modify when I convert the updates from a recursive local variable to a global one. Also deletes a scheduled task from the *INPUT_LIST*. Then it updates the queue of "ready" tasks.

Precedence Graph

62. This procedure loops through the entire *InputList* finding the successors of *Rec*. Once found it updates the *EarliestStartTime*. Also, if the *InDegree* reaches zero this means it no longer is waiting on a predecessor to be scheduled, it is "ready" to be scheduled—that is, moved from the *InputList* to the *ReadyQueue*.

Note: It appears that the *Predecessor* field of the *StepRecord* is ignored. Only the successor field is used.

⟨Procedures and Tasks in *schedtools* 42⟩ +≡

```

procedure CheckInDegree(Rec : in StepRecord; Queue : in out ReadyList; InList : in
    out InputList; finish_t : in natural) is
    Current : StepRecord;
    t : nat_set.set ← Rec.Successors;
    k, kntr : natural;
    FOUND : boolean ← FALSE;
    deleted : boolean ← false;
begin
    if nat_set.size(t) ≠ 0 then
        Rewind(InList); kntr ← ListSize(InList); GetCurrent(InList, Current);
        for i ∈ 1 .. kntr loop
            k ← Current.StepId;
            if nat_set.member(k, t) then
                if Current.EarliestStartTime < finish_t then
                    Current.EarliestStarttime ← finish_t;
                end if;
                Current.InDegree ← Current.InDegree − 1;
                if Current.InDegree = 0 then
                    ⟨Move record from input list to ready list 64⟩

  Current.InDegree ← Current.Indegree + 1;
  InsertInOrder(DeletedInputQueue, Current); deleted ← true;
  if debug then
    put_line("Moving Record to DeletedInputQueue."); Display(DeletedInputQueue);
  end if;

```

This code is used in section 62.

65. StrongFeasible. Checking the feasibility of the schedule with each step in the ready queue.

66. Definition: A partial feasible schedule is said to be *strongly-feasible* if *all* the schedules obtained by extending the current schedule with any one of the remaining tasks are also feasible. Thus, if a partial feasible schedule is found not to be *strongly-feasible* because, say, task *T* misses its deadline when the current schedule is extended by *T*, then it is appropriate to stop the search since none of the future extensions involving task *T* will meet its deadline. In this case, a set of tasks can not be scheduled given the current partial schedule. (In the terminology of branch-and-bound techniques, the search path represented by the current partial schedule is *bound* since it will not lead to a feasible complete schedule.)

⟨Procedures and Tasks in *schedtools* 42⟩ +≡

```

procedure StronglyFeasible(Queue : in out ReadyList; MATRIX : in
    DesignerMatrix; feasible : in out boolean) is
    temp : natural;
    J : natural ← 1;
    L : natural ← 1;
    min : natural ← 0;
    kntr : natural ← 0;
    myonum : natural ← 0;
    Current : StepRecord;
    Myopic_Num : constant natural ← 7;
begin
    if debug then
        put_Line("StronglyFeasible>_Start_");
    end if;

91. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make MAIN work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

92. I enclose the RCS Keywords here as well, since that is how I keep track of versions.

93. Index. Here is a cross-reference table for the `schedtools` package. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

APPENDIX B §

This page intentionally left blank

1. **Introduction.** Here is the Ada code for utilites used in Salah Badr's scheduler program. His program was written by him May 25, 1993. It was translated by John Evans of NRaD into Donald Knuth's WEB format for literate programming. To compile and link the code in its present format you will need the Ada version of the WEB tool.

It is available on-line via the world-wide-web at URL:

<http://white.nosc.mil/~evansjr/literate/>

2. WEB is a literate programming paradigm for C, Pascal or Ada, and other languages. This style of programming is called "Literate Programming." For Further information see the paper *Literate Programming*, by Donald Knuth in *The Computer Journal*, Vol 27, No. 2, 1984; or the book *Weaving a Program: Literate Programming in WEB* by Wayne Sewell, Van Nostrand Reinhold, 1989. Another good source of information is the Usenet group *comp.programming.literate*. It has information on new tools and Frequently Asked Questions (FAQs).

3. Since the original AWEB package was written for Ada '83, it does not properly format new Ada '95 keywords **protected** and **private** . We remedy using the web format commands below.

format protected \equiv *procedure*

format private \equiv *procedure*

4. As a way of explanation, each "Module" withing angle brackets (< >) is expanded somewhere further down in the document. The trailing number you see within the brackets is where you can find this expansion. This provides a type of PDL (program descriptor language) for your program and greatly aids modularity and readability. It is also a highly effective method of top-down programming. The first module here is expanded further down, and contains most of the structure in standard Ada packages.

< Package boiler-plate 5 >

5. Schedule Primitives.

```

< Package boiler-plate 5 > ≡
  output to file schedprims.ads
  with generic_set_pkg;
  with generic_map_pkg;

  use text_io;
  with test_io_pkg;
  use test_io_pkg;
  with Ada.Calendar;
  use Ada.calendar;
  with capability;
  use capability;
  with ustrings;
  use ustrings;
  package schedprims is
    < Instantiate generics 9 >
    < Specification of types and variables visible from schedprims 6 >
    < Specification of procedures visible from schedprims 11 >
  end schedprims;
  output to file schedprims.adb
  with test_io_pkg;
  with calyr;
  use calyr;
  package body schedprims is
    < Variables local to schedprims 25 >
    < Procedures and Tasks in schedprims 26 >
  end schedprims;

```

This code is used in section 4.

6. I make this a *tagged* record so that I can extend it in other packages that inherit this one.

(Specification of types and variables visible from *schedprims* 6) \equiv

```

type StepRecord is tagged record StepID : natural;
  Deadline : natural  $\leftarrow$  0;
  Priority : natural;
  EstimatedDuration : natural  $\leftarrow$  0;
  EarliestStartTime : natural  $\leftarrow$  0;
  ExpLevel : cap_map.map;
  Successors : nat_set.set;
  Predecessors : nat_set.set;
  InDegree : natural  $\leftarrow$  0;
  RecursionLevel : natural  $\leftarrow$  0;
end record;

```

See also sections 7 and 8.

This code is used in section 5.

7.

(Specification of types and variables visible from *schedprims* 6) $+\equiv$

```

type ScheduleRecord is
  record
    StepID : natural;
    StartTime : natural;
    FinishTime : natural;
    Designer : ustring;
    StepLevel : cap_map.map;
    RecursionLevel : natural  $\leftarrow$  0;
  end record;

```

8.

(Specification of types and variables visible from *schedprims* 6) $+\equiv$

```

type CalendarRecord is
  record
    StepID : natural;
    StartTime : Time;
    FinishTime : Time;
    Designer : ustring;
    StepLevel : cap_map.map;
  end record;

```

9. Here is the specification for generics.

```

<Instantiate generics 9> ≡
  package nat_set is new generic_set_pkg(natural,5);
    { Instantiate instances of the generic map package. }
  package nat_map is new generic_map_pkg(key ⇒ natural, result ⇒ natural);
  package set_map is new generic_map_pkg(key ⇒ natural, result ⇒ nat_set.set);
  package exp_map is new generic_map_pkg(key ⇒ natural, result ⇒ ExpertiseLevel);

```

See also section 10.

This code is used in section 5.

10. Here is the specification for generics.

```

<Instantiate generics 9> +≡
  package nat_io is new integer_io(natural);
  procedure put_set is new nat_set.generic_put;
  procedure get_set is new nat_set.generic_input;
  procedure getf_set is new nat_set.generic_file_input;
  package enu_io is new text_io.ENUMERATION_IO(ExpertiseLevel);

```

11. This function is used to compare the *ID* of *StepRecords*

```

<Specification of procedures visible from schedprims 11> ≡
  function CompareID(L1, L2 : StepRecord) return Boolean;

```

See also sections 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, and 23.

This code is used in section 5.

12. This function is used to compare the *ID* of *StepRecords*

```

<Specification of procedures visible from schedprims 11> +≡
  function IsEqual(L1, L2 : StepRecord) return Boolean;

```

13. This function is used to compare the *Deadline* of *StepRecords*

```

<Specification of procedures visible from schedprims 11> +≡
  function CompareDeadLine(L1, L2 : StepRecord) return Boolean;

```

14. This function is used to compare the *Recursion* of *StepRecords*

```

<Specification of procedures visible from schedprims 11> +≡
  function CompareRecursionLevel(L1, L2 : StepRecord) return Boolean;

```

15. This function is used to compare the *StartTime* of *StepRecords*

```

<Specification of procedures visible from schedprims 11> +≡
  function CompareStartTime(L1, L2 : ScheduleRecord) return Boolean;

```

16. This function is used to compare the *StartTime* of *StepRecords*

⟨Specification of procedures visible from *schedprims* 11⟩ +≡

function *CompareStartTime*(*L1*, *L2* : *CalendarRecord*)**return** *Boolean*;

17. Printing a *step* heading line before printing any records.

⟨Specification of procedures visible from *schedprims* 11⟩ +≡

procedure *StepRecordHeading*;

18. Display a record given its *LOCATION* in the list.

⟨Specification of procedures visible from *schedprims* 11⟩ +≡

procedure *DisplayStepRecord*(*rec* : **in** *StepRecord*);

19. Printing a schedule heading line before printing any record.

⟨Specification of procedures visible from *schedprims* 11⟩ +≡

procedure *ScheduleRecordHeading*;

20. Printing a schedule heading line before printing any record.

⟨Specification of procedures visible from *schedprims* 11⟩ +≡

procedure *CalendarRecordHeading*;

21. display a record given its *LOCATION* in the list.

⟨Specification of procedures visible from *schedprims* 11⟩ +≡

procedure *DisplayScheduleRecord*(*Current* : **in** *ScheduleRecord*);

22.

⟨Specification of procedures visible from *schedprims* 11⟩ +≡

procedure *SaveScheduleRecord*(*Current* : **in** *ScheduleRecord*; *fd* : *file_type*);

print_capabilities(*Current.StepLevel*); *text_io.put*("□□");

text_io.put(*S*(*Current.Designer*)); *text_io.new_line*;

end *DisplayCalendarRecord*;

39. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make MAIN work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

40. RCS Keywords.

```
$RCSfile: schedprims.aweb,v
$Revision: 1.4
$Date: 1997/08/22 23:14:45
$Author: evansjr
$Id: schedprims.aweb,v 1.4 1997/08/22 23:14:45 evansjr Exp evansjr
$Locker: evansjr
$State: Exp
```

41. **Index.** Here is a cross-reference table for the MAIN program. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

WEB OUTPUT

APPENDIX C §

This page intentionally left blank

1. Introduction. Here is the Ada code for Salah Badr's scheduler program. It was written by him May 25, 1993. Here it has been translated to Donald Knuth's WEB format for literate programming. To compile and link the code in its present format you will need the Ada version of the WEB tool.

It is available on-line via the world-wide-web at URL:

<http://white.nosc.mil/~evansjr/literate/>

2. WEB is a literate programming paradigm for C, Pascal or Ada, and other languages. This style of programming is called "Literate Programming." For Further information see the paper *Literate Programming*, by Donald Knuth in *The Computer Journal*, Vol 27, No. 2, 1984; or the book *Weaving a Program: Literate Programming in WEB* by Wayne Sewell, Van Nostrand Reinhold, 1989. Another good source of information is the Usenet group *comp.programming.literate*. It has information on new tools and Frequently Asked Questions (FAQs).

3. The program consists of several packages that are declared right now; each of these packages and either the specification and the body of the packages are sent to a separate file. The main program itself is declared later. (Since the original AWEB package was written for Ada '83, it does not properly format new Ada '95 keywords **protected** and **private** . We remedy using the web format commands below.

format *protected* \equiv *procedure*

format *private* \equiv *procedure*

4. As a way of explanation, each "Module" within angle brackets (< >) is expanded somewhere further down in the document. The trailing number you see within the brackets is where you can find this expansion. This provides a type of PDL (program descriptor language) for your program and greatly aids modularity and readability. It is also a highly effective method of top-down programming.

5. **Main driver.** This is the main routine that starts everything.

6. (Note: The following format is used by all the packages. We write the top-level code, in macro-level descriptions, and it gets expanded into code further down. This way you can write small, easily understood modules. It also lets you declare and describe variables and types where you need them.)

```

7. As a way of explanation, each "Module" withing angle brackets (< >) is expanded somewhere further down in the document. The trailing number you see within the brackets is where you can find this expansion. This provides a type of PDL (program descriptor language) for your program and greatly aids modularity and readability. It is also a highly effective method of top-down programming. The first module here is expanded further down, and contains most of the structure in standard Ada packages.

< Package boiler-plate 22 >

8.

< Instantiate generic packages 8 > ≡
 package nat_io is new integer_io(natural);
 use nat_io;

This code is used in section 6.

9.

< Variables local to main 9 > ≡
 type selector_type is new natural range 1 .. 9;
 selector : selector_type ← 1;
 package sel_io is new integer_io(selector_type);
 use sel_io;

See also sections 11 and 13.

This code is used in section 6.

10. This routine has been modified to read in a file and build up the linked list of "steps."

```

⟨ Create new step list 10 ⟩ ≡
  if num_developers > 0 then
    MakeNewStepList(num_developers);
  else
    raise NoDevelopers;
  end if;

```

This code is used in section 6.

11.

```

⟨ Variables local to main 9 ⟩ +≡
  NoDevelopers : exception;

```

12.

```

⟨ Read in developer list 12 ⟩ ≡
  put_line("Please_enter_developer_file_name:");
  get_line(infile);
  get_developers(S(infile)); num_developers ← get_num_developers;

```

This code is used in section 6.

13.

```

⟨ Variables local to main 9 ⟩ +≡
  infile : ustring;
  num_developers : natural ← 0;

```

14.

```

⟨ Schedule steps according to their deadlines 14 ⟩ ≡
  Put_line("Scheduling_steps_according_to_their_deadlines.");
  MakeDeadlineFirstSchedule(maz_recursion, num_developers);

```

This code is used in section 6.

15.

```

⟨ Print all steps in the ready queue 15 ⟩ ≡
  PrintReadyQueue;

```

This code is used in section 6.

16.

```

⟨ Print final schedule 16 ⟩ ≡
  PrintFinalSchedule;

```

This code is used in section 6.

17.

⟨ Save final schedule 17 ⟩ ≡
 SaveFinalSchedule;

This code is used in section 6.

18.

⟨ Print calendar schedule 18 ⟩ ≡
 PrintCalendarSchedule;

This code is used in section 6.

19.

⟨ Print all step records 19 ⟩ ≡
 new_line; *PrintStepList*;

This code is used in section 6.

20.

⟨ Exit the program to the system 20 ⟩ ≡
 put("Maximum_recursion_level_is"); *nat_io.put*(*max_recursion*); *put_line*(".");
 put("Current_recursion_level_is"); *nat_io.put*(*recursion_level*); *put_line*(".");
 put("thank_you....Bye...Bye"); *new_line*; *exit*;

This code is used in section 6.

21.

⟨ Exception handling for selector case 21 ⟩ ≡
 put("_BAD_CHOICE._PLEASE_TRY_AGAIN"); *new_line*;

This code is used in section 6.

22. Scheduler specification.

```

⟨Package boiler-plate 22⟩ ≡
  output to file scheduler.ads
  with generic_set_pkg;
  with generic_map_pkg;
  with generic_list;
  with schedprims;
  use schedprims;
  with schedtools;
  use schedtools;
  with TEXT_IO;
  use TEXT_IO;
  with test_io_pkg;
  use test_io_pkg;

40.

⟨ Procedures and Tasks in *scheduler 33* ⟩ +≡
 procedure *PrintStepList* **is**
 begin
 PrintAllStepRecords(*StepList*);
 end *PrintStepList*;

41. Continuous Time to Calendar Time Translator. The purpose of this routine is to take the output of the scheduler and translate the continuous time fields (*StartTime* and *FinishTime*) to calendar dates.

```

output to file contocal.adb
pragma suppress(all_checks);
with text_io;
use text_io;
with getopt;
use getopt;
with Ustrings;
use Ustrings;
with Ada.Calendar;
use Ada.Calendar;
with calyr;
use calyr;
with capability;
use capability;
procedure ConToCal is
  (Variables local to ConToCal 45)
  package bool_io is new enumeration_io(boolean);
  use bool_io;
begin
  (Get parameters to ConToCal 43)
  (Open files 51)
  (Iterate through input file 53) end ConToCal;
```

42. The command syntax is as follows:

```
contocal [-nrad < boolean >] [-start < startdate >] infile outfile
```

43. The *-nrad* option is by default false, but when set to *true* will create a schedule that respects NRaD off-fridays. An example invocation could be:

```
contocal -nrad true -start 07/03/97+00 infile outfile
```

If no start is given then the default is the same as the example.

```

(Get parameters to ConToCal 43) ≡
  (Get nrad 44)
  (Get start date 46)
  (Get input file 48)
  (Get output file 50)
```

This code is used in section 41.

44.

```

⟨ Get nrad 44 ⟩ ≡
  if option_present(U("-nrad")) then
    get_option(U("-nrad"), param); get(S(param), nrad, Last);
  else
    nrad ← false;
  end if;

```

This code is used in section 43.

45.

```

⟨ Variables local to ConToCal 45 ⟩ ≡
  param : Ustring;
  Last : positive;
  nrad : boolean;

```

See also sections 47, 49, 52, 55, 56, and 58.

This code is used in section 41.

46.

```

⟨ Get start date 46 ⟩ ≡
  if option_present(U("-start")) then
    get_option(U("-start"), param); StartDate ← get_date(param);
  else
    StartDate ← Time_Of(1997, 7, 3, 0.0);
  end if;

```

This code is used in section 43.

47.

```

⟨ Variables local to ConToCal 45 ⟩ +≡
  StartDate : Time;

```

48.

```

⟨ Get input file 48 ⟩ ≡
  if name_present(1) then
    get_name(infile, 1);
  else
    raise nofilename;
  end if;

```

This code is used in section 43.

49.

```
⟨ Variables local to ConToCal 45 ⟩ +≡  
  nofilename : exception;  
  infile, outfile : Ustring;
```

50.

```
⟨ Get output file 50 ⟩ ≡  
  if name_present(2) then  
    get_name(outfile, 2);  
  else  
    raise nofilename;  
  end if;
```

This code is used in section 43.

51.

```
⟨ Open files 51 ⟩ ≡  
  open(data_file, in_file, S(infile)); create(data2_file, out_file, S(outfile));
```

This code is used in section 41.

52.

```
⟨ Variables local to ConToCal 45 ⟩ +≡  
  data_file, data2_file : file_type;
```

53.

```
⟨ Iterate through input file 53 ⟩ ≡  
  while  $\neg$ End_Of_File(data_file) loop  
    ⟨ Read in record 54 ⟩  
    ⟨ Do time translations 57 ⟩  
    ⟨ Write out new record 59 ⟩  
  end loop;
```

This code is used in section 41.

54. A typical input file would look like the following:

3	HIGH	H1	0	3
2	MEDIUM	M1	0	4
1	LOW	L1	0	6
4	HIGH	H1	3	13
5	MEDIUM	M1	4	12
6	LOW	L1	6	10
8	MEDIUM	M1	12	14
7	LOW	L1	10	15
9	HIGH	H1	13	19
10	MEDIUM	M1	14	24

The second to last column is the start time and the last column is the end time.

(Read in record 54) \equiv

```
kntr  $\leftarrow$  kntr + 1; put("Reading in record"); put(kntr); put_line(".");
get(data_file, stepid); get(data_file, Start); get(data_file, Finish);
get_capability(data_file, ExpLevel); get_line(data_file, Developer);
```

This code is used in section 53.

55.

(Variables local to ConToCal 45) \equiv

```
type ExpertiseLevel is (low, medium, high);
stepid : natural;
ExpLevel : cap_map.map;
Developer : ustring;
start, finish : natural;
kntr : natural  $\leftarrow$  0;
```

56.

(Variables local to ConToCal 45) \equiv

```
package exp_io is new enumeration_io(ExpertiseLevel);
use exp_io;
package nat_io is new integer_io(natural);
use nat_io;
```

57.

(Do time translations 57) \equiv

```
dur  $\leftarrow$  ConvertHoursToDuration(Start);
StartTime  $\leftarrow$  DurationToCalendarTime(StartDate, dailyhours, dur, NRaD);
dur  $\leftarrow$  ConvertHoursToDuration(Finish);
FinishTime  $\leftarrow$  DurationToCalendarTime(StartDate, dailyhours, dur, NRaD);
```

This code is used in section 53.

58.

(Variables local to ConToCal 45) \equiv

dur : *Duration*;

StartTime, *FinishTime* : *Time*;

dailyhours : *WorkHours* \leftarrow (*ConvertHoursToDuration*(8), *ConvertHoursToDuration*(8),
 ConvertHoursToDuration(8), *ConvertHoursToDuration*(8),
 ConvertHoursToDuration(8));

59.

(Write out new record 59) \equiv

set_col(*data2_file*, 1); *put*(*data2_file*, *stepid*, 1); *set_col*(*data2_file*, 10);

print_date(*data2_file*, *StartTime*); *set_col*(*data2_file*, 25);

print_date(*data2_file*, *FinishTime*); *set_col*(*data2_file*, 40);

print_capabilities(*data2_file*, *ExpLevel*); *put*(*data2_file*, "□");

put(*data2_file*, *Developer*); *new_line*(*data2_file*);

This code is used in section 53.

60. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make MAIN work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

61. RCS Keywords.

```
$RCSfile: main.aweb,v
$Revision: 1.5
$Date: 1997/08/22 23:14:45
$Author: evansjr
$Id: main.aweb,v 1.5 1997/08/22 23:14:45 evansjr Exp evansjr
$Locker: evansjr
$State: Exp
```

62. Index. Here is a cross-reference table for the MAIN program. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

WEB OUTPUT

Appendix D §

This page intentionally left blank

1. **Introduction.** The scheduler designed and implemented by Salah Badr uses lists extensively. However, it has specific routines for each list used by the scheduler. This is redundant, as well as error prone. In my design to eliminate some large data structures that are slightly modified and duplicated in a very recursive and space consuming manner, I have decided to use additional linked lists to keep track of additions and deletions at each level of recursion. By keeping track of just the “changes” This will turn an N squared space problem into one that is linear. (This is shown to be true, later.)

2. So since linked lists are used extensively, it pays to have a single **generic** routine. The implementation is thus hidden from the user. This allows “information-hiding,” and increased modularity,

3. This code is written using Donald Knuth’s **WEB** paradigm for literate programming. To compile and link the code in its present format you will need the Ada version of the **WEB** tool.

It is available on-line via the world-wide-web at URL:

<http://white.nosc.mil/~evansjr/literate/>

4. **WEB** is a literate programming paradigm for C, Pascal or Ada, and other languages. This style of programming is called “Literate Programming.” For Further information see the paper *Literate Programming*, by Donald Knuth in *The Computer Journal*, Vol 27, No. 2, 1984; or the book *Weaving a Program: Literate Programming in WEB* by Wayne Sewell, Van Nostrand Reinhold, 1989. Another good source of information is the Usenet group *comp.programming.literate*. It has information on new tools and Frequently Asked Questions (FAQs).

5. The program consists of several packages that are declared right now; each of these packages and either the specification and the body of the packages are sent to a separate file. The main program itself is declared later. (Since the original AWEB package was written for Ada '83, it does not properly format new Ada '95 keywords **protected** and **private** . We remedy using the web format commands below.

```
format protected ≡ procedure
format private ≡ procedure
```

6. As a way of explanation, each “Module” withing angle brackets (< >) is expanded somewhere further down in the document. The trailing number you see within the brackets is where you can find this expansion. It is top-down in appearance, and in actual fact.

7. All the modules follow the same, top-down format. I will group all the boiler-plate into one module, for the compiler, but you will see it with the packages, as they are described.

(Package boiler-plate 8)

8. List Specification. This specification is a modification of the one presented in the book *Ada 95 Problem Solving and Program Design*, by Michael Feldman and Elliot B. Koffman. The implementation was left as an exercise for the student.

```

< Package boiler-plate 8 > ≡
  output to file generic_list.ads
  with TEXT_IO;
  use TEXT_IO;
  generic
  type ElementType is private ; { Any nonlimited type will do }
  with procedure DisplayElement(Item : IN ElementType);
  with function "<"(L1, L2 : ElementType) return Boolean;
  with function "="(L1, L2 : ElementType) return Boolean is <>;
  package generic_list is
    < Specification of types and variables visible from generic_list 9 > < Specification of
      procedures visible from generic_list 12 > private
    < Specification of private types and variables in generic_list 10 >
  end generic_list;
  output to file generic_list.adb
  < Packages needed by generic_list body 32 >
  package body generic_list is
    < Variables local to generic_list 30 >
    < Procedures and Tasks in generic_list 33 >
  end generic_list;

```

This code is used in section 7.

9.

```

< Specification of types and variables visible from generic_list 9 > ≡
  type list is limited private ;
  ListEmpty : exception;

```

This code is used in section 8.

10.

```

< Specification of private types and variables in generic_list 10 > ≡
  type ListNode; type ListPtr is access ListNode;
  type ListNode is
    record
      Element : ElementType;
      Next : ListPtr;
    end record;

```

See also section 11.

This code is used in section 8.

11. Added *Size* field to original code.

⟨ Specification of private types and variables in *generic_list 10* ⟩ +≡

```

type List is
  record
    Size : Natural;
    Head : ListPtr;
    Tail : ListPtr;
    Current : ListPtr;
    Previous : ListPtr;
  end record;

```

12.

⟨ Specification of procedures visible from *generic_list 12* ⟩ ≡

```

function ListSize(L : in List) return natural;

```

See also sections 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, and 28.

This code is used in section 8.

13. Returns *True* if *L* is empty, *False* otherwise.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡

```

function IsEmpty(L : IN List) RETURN Boolean;

```

14.

Pre: *Element* is defined; *L* may be empty.

Post: *Element* is inserted at the beginning of *L*.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡

```

procedure AddToFront(L : in out List; Element : in ElementType);

```

15.

Pre: *L* is defined; *L* may be empty.

Post: returns a complete copy of the list *L*.

Raises: *ListEmpty* if the list is empty before the retrieval.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡

```

function RetrieveFront(L : in List) return ElementType;

```

16.

Pre: *L* is defined; *L* may be empty.

Post: The first node of *L* is removed.

Raises: *ListEmpty* if the list is empty before the removal.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡

```

procedure RemoveFront(L : in out List);

```

17.

Pre: *L* is defined.Post: *L* is empty.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *MakeEmpty*(*L* : in out *List*);

18.

Pre: *Element* is defined; *L* may be empty.Post: *Element* is appended to the end of *L*.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *AddToEnd*(*L* : in out *List*; *Element* : in *ElementType*);

19.

Pre: Source may be empty.

Post: Returns a complete copy of Source in Target.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *Copy*(*Source* : in *List*; *Target* : out *List*);

20.

Pre: *L* may be empty.Post: displays the contents of *L*'s *Element* fields, in the order in which they appear in *L*.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *Display*(*L* : IN *List*);

21.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *InsertInOrder*(*L* : in out *List*; *Element* : *ElementType*);

22.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *GetNext*(*L* : in out *List*; *Element* : out *ElementType*);

23.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *DeleteCurrent*(*L* : in out *List*);

24.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *DeleteMatching*(*L* : in out *List*; *Element* : in *ElementType*; *success* : out *boolean*);

25.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *GetCurrent*(*L* : in *List*; *Element* : out *ElementType*);

26.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *UpdateCurrent*(*L* : in *List*; *Element* : in *ElementType*);

27.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *GetNth*(*L* : in out *List*; *N* : in *natural*; *Element* : out *ElementType*);

28.

⟨ Specification of procedures visible from *generic_list 12* ⟩ +≡
procedure *Rewind*(*L* : in out *List*);

29. List Body.**30.**

⟨ Variables local to *generic_list* 30 ⟩ ≡
debug : *boolean* ← *false*;

See also section 31.

This code is used in section 8.

31.

⟨ Variables local to *generic_list* 30 ⟩ +≡
procedure *Dispose* **is new** *unchecked_deallocation* (*Object* ⇒ *ListNode*,
Name ⇒ *ListPtr*);
package *nat.io* **is new** *integer_io* (*natural*);

32.

⟨ Packages needed by *generic_list* body 32 ⟩ ≡
with *unchecked_deallocation*;
with *Ustrings*;
use *Ustrings*;

This code is used in section 8.

33.

⟨ Procedures and Tasks in *generic_list* 33 ⟩ ≡
function *ListSize* (*L* : *in List*) **return** *Natural* **is**
begin
 return *L.Size*;
end *ListSize*;

See also sections 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, and 49.

This code is used in section 8.

34. Returns *True* if *L* is empty, *False* otherwise.

⟨ Procedures and Tasks in *generic_list* 33 ⟩ +≡
function *IsEmpty* (*L* : *IN List*) **RETURN** *Boolean* **is**
begin
 if *ListSize* (*L*) = 0 **then**
 return *True*;
 else
 return *False*;
 end if;
end *IsEmpty*;

35.

Pre: *Element* is defined; *L* may be empty.Post: *Element* is inserted at the beginning of *L*.(Procedures and Tasks in *generic_list* 33) +≡**procedure** *AddToFront*(*L* : in out *List*; *Element* : in *ElementType*) **is***Temp* : *ListPtr*;**begin***Temp* ← new *ListNode*; *Temp.all.Element* ← *Element*; *Temp.all.Next* ← *L.Head*;*L.Head* ← *Temp*; *L.Size* ← *L.Size* + 1;**if** *L.Size* = 1 **then***L.Tail* ← *L.Head*;**end if**;**end** *AddToFront*;

36.

Pre: *L* is defined; *L* may be empty.Post: returns a complete copy of the list *L*.Raises: *ListEmpty* if the list is empty before the retrieval.(Procedures and Tasks in *generic_list* 33) +≡**function** *RetrieveFront*(*L* : in *List*) **return** *ElementType* **is***Temp* : *ListPtr*;**begin****if** *L.Head* = null **then****raise** *ListEmpty*;**else** { *L.Head* points to a node; remove it }*Temp* ← *L.Head*; **return** *Temp.Element*;**end if**;**end** *RetrieveFront*;

37.

Pre: L is defined; L may be empty.Post: The first node of L is removed.Raises: *ListEmpty* if the list is empty before the removal.

(Procedures and Tasks in *generic_list* 33) \equiv
procedure *RemoveFront*(L : in out *List*) is
 $Temp$: *ListPtr*;
begin
 if $L.Head = \text{null}$ **then**
 raise *ListEmpty*;
 else { $L.Head$ points to a node; remove it }
 $Temp \leftarrow L.Head$; $L.Head \leftarrow L.Head.all.Next$; {jump around first node}

 end if;
end *RemoveFront*;

38.

(Procedures and Tasks in *generic_list* 33) \equiv
procedure *MakeEmpty*(L : IN OUT *List*) is
 ptr : *ListPtr*;
begin
 While $L.Head \neq \text{null}$ **loop**
 $RemoveFront(L)$;
 end loop;
 $L.Size \leftarrow 0$; $L.Tail \leftarrow \text{null}$;
end *MakeEmpty*;

39.

Pre: *Element* is defined; *L* may be empty.Post: *Element* is appended to the end of *L*.(Procedures and Tasks in *generic_list 33*) +≡

```

procedure AddToEnd(L : IN OUT List; Element : IN ElementType) is
  ptr : ListPtr;
begin
  if debug then
    put("AddToEnd>_Adding_to_end_of_list:_"); DisplayElement(Element);
  end if;
  if L.Head = null then
    L.Tail ← new ListNode'(Element, null); L.Head ← L.Tail;
  else
    ptr ← new ListNode'(Element, null); L.Tail.all.next ← ptr; L.Tail ← ptr;
  end if;
  L.Size ← L.Size + 1;
end AddToEnd;

```

40.

Pre: Source may be empty.

Post: Returns a complete copy of Source in Target.

(Procedures and Tasks in *generic_list 33*) +≡

```

procedure Copy(Source : in List; Target : out List) is
  ptr : listptr;
begin
  ptr ← Source.head; MakeEmpty(Target);
  while ptr ≠ null loop
    AddToEnd(Target, ptr.all.element); ptr ← ptr.all.next;
  end loop;
end Copy;

```

41.

Pre: *L* may be empty.

Post: displays the contents of *L*'s *Element* fields, in the order in which they appear in *L*.

(Procedures and Tasks in *generic_list* 33) +≡

procedure *Display*(*L* : *IN List*) **is**

ptr : *ListPtr*;

begin

if *debug* **then**

put_Line("Display>");

end if;

ptr ← *L.Head*;

while *ptr* ≠ null **loop**

DisplayElement(*ptr.all.Element*); *ptr* ← *ptr.all.Next*;

end loop;

end *Display*;

42.

(Procedures and Tasks in *generic_list* 33) +≡

```

procedure InsertInOrder(L : in out List; Element : ElementType) is
  Current : ListPtr;
  Previous : ListPtr;
  Temp : ListPtr;
begin
  if debug then
    put("InsertInOrder>"); put_Line("Your_input_list_is:"); display(L);
    put("InsertInOrder>"); put_Line("Your_input_element_is:");
    displayelement(Element);
  end if;
  if L.Head = null then
    AddToFront(L, Element);
  elsif Element < L.Head.all.Element then
    AddToFront(L, Element);
  elsif (L.Tail.all.Element < Element) ∨ (L.Size = 1) then
    AddToEnd(L, Element);
  else

  L.Current.all.element ← Element;
end UpdateCurrent;

```

46.

(Procedures and Tasks in *generic_list* 33) +≡

```

procedure DeleteCurrent(L : in out List) is
  Temp : ListPtr;
begin
  if L.Head = null then
    raise ListEmpty;
  elsif L.Size = 1 then
    Temp ← L.Current; L.Current ← null; L.Previous ← null; L.Head ← null;
    L.Tail ← null;
  else
    Temp ← L.Current;
    if L.Current = L.Tail then
      L.Previous.all.next ← L.Current.all.next; L.Current ← L.Head;
      L.Tail ← L.Previous;
    elsif L.Current = L.Head then
      L.Current ← L.Current.all.Next; {jump around current node}
      L.Head ← L.Current;
    else
      L.Previous.all.next ← L.Current.all.next; L.Current ← L.Current.all.Next;
      {jump around current node}
    end if;
  end if;
  if debug then
    put("DeleteCurrent>Deleting=>"); DisplayElement(Temp.all.Element);
  end if;
  Dispose(X ⇒ Temp); L.Size ← L.Size - 1;
end DeleteCurrent;

```

47.

⟨Procedures and Tasks in *generic_list* 33⟩ +≡

```

procedure DeleteMatching(L : in out List; Element : in ElementType; success : out
    boolean) is
    kntr : natural;
    Current : ElementType;
begin
    success ← false;
    if L.Head = null then
        raise ListEmpty;
    end if;
    Rewind(L); kntr ← L.Size;
    for i ∈ 1 .. kntr loop
        GetNext(L, Current);
        if Current = Element then
            DeleteCurrent(L); success ← true; exit;
        end if;
    end loop;
end DeleteMatching;

```

48.

⟨Procedures and Tasks in *generic_list* 33⟩ +≡

```

procedure Rewind(L : in out List) is
begin
    L.Current ← L.Head; L.Previous ← L.Tail;
end Rewind;

```

49. Must be used with *ListSize* and *Rewind* or you will never know when you are at the end of the list.

⟨Procedures and Tasks in *generic_list* 33⟩ +≡

```

procedure GetNext(L : in out List; Element : out ElementType) is
begin
    if L.Head = null then
        raise ListEmpty;
    elsif L.Current = L.Tail then
        L.Current ← L.Head; L.Previous ← L.Tail;
    else
        L.Previous ← L.Current; L.Current ← L.Current.all.next;
    end if;
    Element ← L.Current.all.element;
end GetNext;

```

50. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make MAIN work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

51. RCS Keywords.

```
$RCSfile: list.aweb,v
$Revision: 1.4
$Date: 1997/08/06 16:54:30
$Author: evansjr
$Id: list.aweb,v 1.4 1997/08/06 16:54:30 evansjr Exp evansjr
$Locker: evansjr
$State: Exp
```

52. Index. Here is a cross-reference table for the MAIN program. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

APPENDIX E §

This page intentionally left blank

1. **Introduction.** This package computes federal holidays, and off-fridays for NRaD. (We work five days one week, four the next—nine hours a day, except for Fridays.) The input is just the year. If you do not work the 5/4 weeks then there is a switch (`-nps true`) that you can use to turn it off.

2. This is based on a C program *calyr*, written by Bob Hall of Nrad in the eighties. Bob was a brilliant, and prolific programmer at NRaD who retired in the early nineties. One of his programs *msgs*, formed the basis of *Eudora*, a popular mail tool for PC's and Macintoshes, and now owned by Qualcomm.

3. This program was written to work for dates after 1970. It should work till the year 2099. (A year 3000 problem!) To test it out compile the driver program and run it with the following command line:

```
main [-year <year>] [-nps <boolean>]
```

For example:

```
main -year 1993 -nps false
```

4. This code is written using Donald Knuth's **WEB** paradigm for literate programming. To compile and link the code in its present format you will need the Ada version of the **WEB** tool.

It is available on-line via the world-wide-web at URL:

```
http://white.nosc.mil/~evansjr/literate/
```

. p

5. **WEB** is a literate programming paradigm for C, Pascal or Ada, and other languages. This style of programming is called "Literate Programming." For Further information see the paper *Literate Programming*, by Donald Knuth in *The Computer Journal*, Vol 27, No. 2, 1984; or the book *Weaving a Program: Literate Programming in WEB* by Wayne Sewell, Van Nostrand Reinhold, 1989. Another good source of information is the Usenet group *comp.programming.literate*. It has information on new tools and Frequently Asked Questions (FAQs).

6. The program consists of several packages that are declared right now; each of these packages and either the specification and the body of the packages are sent to a separate file. The main program itself is declared later. (Since the original AWEB package was written for Ada '83, it does not properly format new Ada '95 keywords **protected** and **private** . We remedy using the web format commands below.

```
format protected ≡ procedure
```

```
format private ≡ procedure
```

7. As a way of explanation, each "Module" withing angle brackets (< >) is expanded somewhere further down in the document. Consider it a high-level PDL (Program Descriptor Language). The trailing number you see within the brackets is where you can find this expansion. It is top-down in appearance, and in actual fact.

8. All the modules follow the same, top-down format. I will group all the boiler-plate into one module, for the compiler, but you will see it with the packages, as they are described.

⟨ Package boiler-plate 9 ⟩

9. Calyr Specification.

16.

< Specification of procedures visible from *calyr 16* > ≡
procedure *print_holidays* (*yr* : **in** *Year_Number*; *do_nps* : **in** *boolean*);

See also sections 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, and 30.

This code is used in section 9.

17. Given a date (in Ada time format), *holDy* returns any special info about it.

status return values:	0	not a special day
	1	a non-work holiday
	2	observation of a non-work holiday
	3	other special day (not non-work)
	4	an off-Friday or Thursday
di return values:	di[0]	weekday of holiday (0 to 6)
	di[1]	day identification index
	di[2]	2: off-Friday; 1 : off-Thursday
		0: not an offday

< Specification of procedures visible from *calyr 16* > +≡
procedure *holDy* (*yrdate* : *time*; *di* : **out** *threearray*; *status* : **out** *integer*);

18. This function was taken from the book *Numerical Recipes*. It actually works on any year, not the artificial limit imposed by Ada type *Year_Number* (1901 .. 2099).

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
function julian_day(Month : Month_Number; Day : Day_Number; Year : Integer)return
    long_integer;
```

19. This procedure calculates the Month, Day, and Year when given the *Julian_day*.

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
procedure caldate(Julian : Long_integer; Month : out Month_Number; Day : out
    Day_Number; Year : out Integer);
```

20. Computes whether this is an off-day or a work-day.

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
function IsWorkDay(YrDate : Time; NRaD : boolean ← false;
    debugit : boolean ← false)return boolean;
```

21. Function aid computing new dates based on work hours.

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
function DurationToCalendarTime(StartDate : Time; dailyhours : WorkHours;
    hrs : Duration; NRaD : boolean)return Time;
```

22. Inverse of above.

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
function CalendarTimeToDuration(StartDate : Time; dailyhours : WorkHours;
    EndDate : Time; NRaD : boolean)return Duration;
```

23.

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
function SameDay(Time1, Time2 : Time)return boolean;
```

24.

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
function GetDayOfWeek(Today : Time)return DayOfWeek;
```

25. Straightforward transformation.

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
function ConvertHoursToDuration(hrs : natural)return Duration;
```

26. Inverse of previous.

⟨Specification of procedures visible from *calyr 16*⟩ +≡

```
function ConvertDurationToHours(dur : Duration)return natural;
```

27.

⟨ Specification of procedures visible from *calyr 16* ⟩ +≡

Procedure Split(Seconds : Day_Duration; Hour : out Hour_Number; Minute : out Minute_Number; Second : out Second_Number);

28.

⟨ Specification of procedures visible from *calyr 16* ⟩ +≡

procedure print_date(date : time);
procedure print_date(outfile : file_type; date : time);

29.

⟨ Specification of procedures visible from *calyr 16* ⟩ +≡

function get_date(str : in Ustring) return Time;
function get_date(infile : file_type) return Time;

30. Adds one day to the input parameter.

⟨ Specification of procedures visible from *calyr 16* ⟩ +≡

function IncrementDay(YrDate : Time) return Time;

31. Calyr Body.**32.**

\langle Packages needed by *calyr* body 10 $\rangle + \equiv$
 with *Ada.Strings.Unbounded*; Use *Ada.Strings.Unbounded*; with *Ustrings*;
 use *Ustrings*;

33. Number days in the month.

\langle Variables local to *calyr* 33 $\rangle \equiv$

38.

```

⟨ Variables local to calyr 33 ⟩ +≡
  debug : boolean ← false;
  debug2 : boolean ← false;
  verbose : boolean ← true;
  nps : boolean ← false;
  already_leaped : boolean ← false;
  package int_io is new integer_io(integer);
  use int_io;

```

39.

```

⟨ Procedures and Tasks in calyr 39 ⟩ ≡
  procedure hoLdy(yrdate : time; di : out threearray; status : out integer) is
    ⟨ Types and Variables local to hoLdy 41 ⟩
  begin
    ⟨ Parse date 40 ⟩
    ⟨ Check if leap year 42 ⟩
    ⟨ Set year 43 ⟩
    ⟨ Set month 63 ⟩
    ⟨ Loop over holidays and Off-Fridays 67 ⟩
  end hoLdy;

```

See also sections 81, 88, 93, 101, 109, 118, 129, 131, 132, 133, 134, 136, 137, 139, 141, and 143.

This code is used in section 9.

40.

```

⟨ Parse date 40 ⟩ ≡
  Split(yrdate, Year, Month, Day, Seconds); hmn ← Calyr.month'val(Month - 1);
  status ← 0; di(0) ← 0; di(1) ← 0; di(2) ← 0;

```

This code is used in section 39.

41.

```

⟨ Types and Variables local to hoLdy 41 ⟩ ≡
  Year : Year_Number;
  Month : Month_Number;
  Day : Day_Number;
  Seconds : Day_Duration;
  hmn : Calyr.Month;

```

See also sections 45, 64, 68, and 71.

This code is used in section 39.

42. Simple-minded check. Must later look up what to do at end of century.

```

< Check if leap year 42 > ≡
  if ((Year mod 4) = 0) ∧ (¬already_leaped) then
    already_leaped ← true; ndm(calyr.month'pos(Feb) + 1) ← 29;
    for j ∈ 3 .. 12 loop
      ldpm(j) ← ldpm(j) + 1;
    end loop;
  end if;

```

This code is used in section 39.

43. The datatype *hol* must be modified based on the year. The following code does just that.

```

< Set year 43 > ≡
  < Calculate weekday of Jan 1. 44 >
  < Calculate beginning date of 1st pay period in year 47 >
  < Update ML King Day 51 >
  < Update President's Day 52 >
  < Update Memorial Day 53 >
  < Update Columbus Day 54 >
  < Update Veteran's Day 55 >
  < Compute Easter 56 >

```

This code is used in section 39.

44.

```

< Calculate weekday of Jan 1. 44 > ≡
  jul := julian_day(1, 1, Year); fdy ← DayOfWeek'val((jul + 1) mod 7);
  jul := julian_day(Month, Day, Year); di(1) ← integer((jul + 1) mod 7);

```

This code is used in section 43.

45.

```

< Types and Variables local to hol.dy 41 > +≡
  jul : long-integer;

```

46. Make global.

```

< Variables local to calyr 33 > +≡
  fdy : DayOfWeek;

```

47. Funny C logic. Seems to work.

```

⟨ Calculate beginning date of 1st pay period in year 47 ⟩ ≡
  tYear ← Year - 1970; tmp ← (Year - 1) rem 4;
  if tmp = 0 then
    tmp ← 1;
  else
    tmp ← 0;
  end if;
  bpp ← (11 - tYear - tmp - (tYear/4)) rem 14;
  if bpp < 1 then
    bpp ← bpp + 14;
  end if;

```

This code is used in section 43.

48. Make global.

```

⟨ Variables local to calyr 33 ⟩ +≡
  bpp : integer;
  tYear : integer;
  tmp : integer;

```

49.

```

⟨ Variables local to calyr 33 ⟩ +≡
  type hol_type is
    record
      dy : fourarray; { Day of week or date of holiday }
      wn : fourarray; { Week number (-1 -i skip }
      fl : fourarray; { 1/0 -i non-work/work holiday }
      iz : fourarray; { Index of holiday name }
    end record;

```

50. I know this is ugly, but it comes directly from C code.

```

< Variables local to calyr 33 > +≡
  hol : array (Month) of holtype ← (((1, DayOfWeek'pos(MON), -1, 0), (0, 3, 0, 0), (1,
    1, 0, 0), (JNYD, JMLK, 0, 0)), ((14, DayOfWeek'pos(MON), -1, 0), (0, 3, 0, 0), (0, 1,
    0, 0), (JVAL, JPRS, 0, 0)), ((17, 0, 0, -1), (0, -1, -1, 0), (0, 0, 0, 0), (JSPT, JGFR,
    JEST, 0)), ((0, 0, 0, -1), (-1, -1, -1, 0), (0, 0, 0, 0), (0, JGFR, JEST, 0)),
    ((DayOfWeek'pos(SUN), DayOfWeek'pos(SAT), DayOfWeek'pos(MON), -1), (2,
    3, 5, 0), (0, 0, 1, 0), (JMOT, JAFD, JMEM, 0)), ((14, DayOfWeek'pos(SUN), -1, 0),
    (0, 3, 0, 0), (0, 0, 0, 0), (JFLG, JFAT, 0, 0)), ((4, -1, 0, 0), (0, 0, 0, 0), (1, 0, 0, 0), (JIND,
    0, 0, 0)), ((-1, 0, 0, 0), (0, 0, 0, 0), (0, 0, 0, 0), (0, 0, 0, 0)), ((DayOfWeek'pos(MON),
    -1, 0, 0), (1, 0, 0, 0), (1, 0, 0, 0), (JLAB, 0, 0, 0)), ((DayOfWeek'pos(MON),
    DayOfWeek'pos(MON), 31, -1), (2, -1, 0, 0), (1, 1, 0, 0), (JCOL, JVET, JHAL, 0)),
    ((DayOfWeek'pos(TUE), 11, DayOfWeek'pos(THU), -1), (-1, 0, 4, 0), (0, 1, 1, 0),
    (JELC, JVET, JTHX, 0)), ((25, -1, 0, 0), (0, 0, 0, 0), (1, 0, 0, 0), (JCHR, 0, 0, 0)));

```

51. ML King Day became federal holiday in 1986.

```

< Update ML King Day 51 > ≡
  if Year > 1985 then
    hol(JAN).wn(IMLK) ← 3;
  else
    hol(JAN).wn(IMLK) ← -1;
  end if;

```

This code is used in section 43.

52. President's day is third Monday (after 1971).

```

< Update President's Day 52 > ≡
  hol(Feb).dy(IPRS) ← DayOfWeek'pos(Mon); hol(Feb).wn(IPRS) ← 3;
  if (Year < 1971) then
    hol(Feb).dy(IPRS) ← 22; hol(Feb).wn(IPRS) ← 0;
  end if;

```

This code is used in section 43.

53. Memorial Day is last Monday in May.

```

< Update Memorial Day 53 > ≡
  hol(May).dy(IMEM) ← DayOfWeek'pos(Mon); hol(May).wn(IMEM) ← 5;

```

This code is used in section 43.

54. Columbus Day is second Monday in October. Did not exist before 1971, I guess?

```

<Update Columbus Day 54> ≡
  hol(Oct).wn(ICOL) ← 2;
  if Year < 1971 then
    hol(Oct).wn(ICOL) ← -1;
  end if;

```

This code is used in section 43.

55.

```

<Update Veteran's Day 55> ≡
  hol(Oct).wn(IVET) ← -1; hol(Nov).wn(IVET) ← 0;
  if Year < 1978 then
    hol(Oct).wn(IVET) ← 4; hol(Nov).wn(IVET) ← -1;
  end if;

```

This code is used in section 43.

56. Calls the function Easter. Also computes Good Friday.

```

<Compute Easter 56> ≡
  edt ← easter(Year); hol(edt.mn).dy(IEST) ← edt.dt; hol(edt.mn).wn(IEST) ← 0;
  edt.dt ← edt.dt - 2;
  if edt.dt < 1 then
    edt.dt ← edt.dt + ndm(3); edt.mn ← Mar;
  end if;
  hol(edt.mn).dy(IGFR) ← edt.dt; hol(edt.mn).wn(IGFR) ← 0;

```

This code is used in section 43.

57.

```

<Types local to calyr 57> ≡
  type caldat is
    record
      mn : Month;
      dt : integer;
    end record;

```

This code is used in section 9.

58.

```

<Variables local to calyr 33> +≡
  edt : caldat;

```

59. Here is the function *easter* that returns the day and month Easter occurs for a given year.

```

< Local Procedures 59 > ≡
  function easter(Year : in Year_Number) return caldat is
    < Types and variables local to easter 60 >
  begin
    fde ← ndm(1) + ndm(2); dt.dt ← pfm((Year - 1900) mod 19);
    if dt.dt < 0 then
      dt.mn ← Mar; dt.dt ← -dt.dt;
    else
      dt.mn ← Apr; fde ← fde + ndm(3);
    end if;
    < Compute weekday for Paschal Full Moon 62 >
    return dt;
  end easter;

```

This code is used in section 9.

60. Here is the Paschal Full Moon table used to find Easter.

```

< Types and variables local to easter 60 > ≡
  pfm : constant array (0 .. 18) of integer ← (14, 3, -23, 11, -31, 18, 8, -28, 16, 5, -25,
    13, 2, -22, 10, -30, 17, 7, -27);

```

See also section 61.

This code is used in section 59.

61.

```

< Types and variables local to easter 60 > +≡
  fde : integer;
  dt : caldat;

```

62. Easter is the next Sunday following the Paschal Full Moon.

```

< Compute weekday for Paschal Full Moon 62 > ≡
  fde ← (dt.dt + fde - (8 - DayOfWeek'pos(fdy))) rem 7;
  if fde < 0 then
    fde ← (7 + fde) rem 7;
  end if;
  dt.dt ← dt.dt + 7 - fde;
  if dt.dt > ndm(month'pos(dt.mn) + 1) then
    dt.dt ← dt.dt - ndm(month'pos(dt.mn) + 1); dt.mn ← month'succ(dt.mn);
  end if;

```

This code is used in section 59.

63. Used to determine off-fridays of month. Also, if November, figure out election day.

$\langle \text{Set month 63} \rangle \equiv$

declare

ldm, ofr, ii, jj : integer;

  Minute_Number;
  Second : out Second_Number) is yrsecs : Day_Duration ← Seconds;
begin
  Hour ← integer(yrsecs)/3600; yrsecs ← yrsecs - Duration(Hour * 3600);
  Minute ← integer(yrsecs)/60; yrsecs ← yrsecs - Duration(Minute * 60);
  Second ← integer(yrsecs);
end Split;
```

135. Prints out the date.

mm	Month number
dd	Day number in the month
HH	Hour number (24 hour system)
MM	Minute number
SS	Second number
cc	Century minus one
yy	Last 2 digits of the year number

The month, day, year, and century may be omitted; the current values are applied as defaults. For example:

date 10080045

sets the date to Oct 8, 12:45 a.m. The current year is the default because no year is supplied.

136. This was written because there seemed to be an error in adding 86,400.0 seconds to a day and then expecting the answer to come out right. Errors occurred around April 7, 1997 and October 26, 1997. I believe it is a GNAT bug for version 3.09.

  nps : boolean;
```

This code is used in section 146.

151. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make MAIN work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

152. RCS Keywords.

```
$RCSfile: calyr.aweb,v
$Revision: 1.1
$Date: 1997/08/18 22:43:35
$Author: evansjr
$Id: calyr.aweb,v 1.1 1997/08/18 22:43:35 evansjr Exp evansjr
$Locker: evansjr
$State: Exp
```

153. Index. Here is a cross-reference table for the MAIN program. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

APPENDIX F §

This page intentionally left blank

1. **Introduction.** Here is the Ada code for routines used in calculating probability distributions. This code uses Donald Knuth's **WEB** format for literate programming. To compile and link the code in its present format you will need the Ada version of the **WEB** tool.

It is available on-line via the world-wide-web at URL:

<http://white.nosc.mil/~evansjr/literate/>

2. **WEB** is a literate programming paradigm for C, Pascal or Ada, and other languages. This style of programming is called "Literate Programming." For Further information see the paper *Literate Programming*, by Donald Knuth in *The Computer Journal*, Vol 27, No. 2, 1984; or the book *Weaving a Program: Literate Programming in WEB* by Wayne Sewell, Van Nostrand Reinhold, 1989. Another good source of information is the Usenet group *comp.programming.literate*. It has information on new tools and Frequently Asked Questions (FAQs).

3. The program consists of several packages that are declared right now; each of these packages and either the specification and the body of the packages are sent to a separate file. The main program itself is declared later. (Since the original AWEB package was written for Ada '83, it does not properly format new Ada '95 keywords **protected** and **private**. We remedy using the web format commands below.

format protected \equiv *procedure*

format private \equiv *procedure*

4. As a way of explanation, each "Module" withing angle brackets (< >) is expanded somewhere further down in the document. The trailing number you see within the brackets is where you can find this expansion. You can treat the modules names as a PDL (Program Descriptor Language), a highly recommened way of writing and documenting code.

(Package boiler-plate 5)

5. Probability Primitives.

```

< Package boiler-plate 5 > ≡
  output to file probability.ads
  < Needed packages 6 >
  package probability is
    < Specification of types and variables visible from probability 7 >
    < Specification of procedures visible from probability 8 >
  end probability;
  output to file probability.adb
  package body probability is
    < Variables local to probability 10 >
    < Procedures and Tasks in probability 11 >
  end probability;

```

This code is used in section 4.

6. Here is the specification for generics.

```

< Needed packages 6 > ≡
  with Ada.Numerics.Float_Random;

```

See also section 12.

This code is used in section 5.

7.

```

< Specification of types and variables visible from probability 7 > ≡
  type bool_array is array (integer range <>) of boolean;

```

This code is used in section 5.

8.

```

< Specification of procedures visible from probability 8 > ≡
  function Uniform(Low, High : Float) return float;
  function Uniform(Low, High : Natural) return Natural;
  procedure sample(M, N : in natural; yrsample : out bool_array);

```

This code is used in section 5.

9. Probability functions Body.**10.**

\langle Variables local to *probability 10* $\rangle \equiv$
debug : *boolean* \leftarrow *false*;
FirstTime : *boolean* \leftarrow *true*;

This code is used in section 5.

11.

\langle Procedures and Tasks in *probability 11* $\rangle \equiv$
function *Uniform*(*Low*, *High* : *Float*) **return** *float* **is**
 use *Ada.Numerics.Float_Random*;
 P1 : *Uniformly_Distributed*;
 G : *Generator*;
 answer : *float*;
 tmp : *float*;
 begin
 Reset(*G*); *P1* \leftarrow *Random*(*G*); *tmp* \leftarrow (*High* - *Low*); *answer* \leftarrow *tmp* * (*P1*) + *Low*;
 return *answer*;
 end *Uniform*;

See also sections 13 and 14.

This code is used in section 5.

12.

\langle Needed packages 6 $\rangle + \equiv$
 with *Text_IO*;
 use *Text_IO*;

13.

⟨ Procedures and Tasks in *probability 11* ⟩ +≡

```

function Uniform(Low, High : natural) return natural is
  use Ada.Numerics.Float_Random;
  P1 : Uniformly_Distributed;
  G : Generator;
  tmp, tmp2 : float;
  answer : natural;
  package flt_io is new float_io(float);
  use flt_io;
begin
  if Low = High then
    answer ← Low;
  else
    if FirstTime then
      Reset(G, 68069); FirstTime ← false;
    else
      Reset(G);
    end if;
    P1 ← Random(G); tmp ← float(High - Low + 1); tmp2 ← (tmp * P1) - 0.5;
    if (debug) then
      put("Random_ generated_"); put(P1); put_line("._");
      put("(high-low+1)_ tmp_ =_"); put(tmp); put_line("._");
      put("(tmp*p1)_ tmp2_ =_"); put(tmp2); put_line("._");
    end if;
    answer ← natural(tmp2) + Low;
  end if;
  return answer;
end Uniform;

```

14. Based on a routine from the September, 1987 *Communications of the ACM*.

(Procedures and Tasks in *probability 11*) \equiv

procedure *sample*(*M, N* : *in natural*; *yrsample* : *out bool_array*) **is**

t : *natural*;

k : *natural*;

begin

for *j* \in 1 .. *N* **loop**

yrsample(*j*) \leftarrow *false*;

end loop;

k \leftarrow *N* - *M* + 1;

for *j* \in *k* .. *N* **loop**

t \leftarrow *uniform*(1, *j*);

if *yrsample*(*t*) **then**

yrsample(*j*) \leftarrow *true*;

else

yrsample(*t*) \leftarrow *true*;

end if;

end loop;

end *sample*;

15. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make MAIN work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

16. RCS Keywords.

```
$RCSfile: probability.aweb,v
$Revision: 1.1
$Date: 1997/08/03 21:35:14
$Author: evansjr
$Id: probability.aweb,v 1.1 1997/08/03 21:35:14 evansjr Exp evansjr
$Locker: evansjr
$State: Exp
```

17. Index. Here is a cross-reference table for the MAIN program. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

We remedy using the web format commands below.

format protected \equiv *procedure*

format private \equiv *procedure*

5. As a way of explanation, each "Module" withing angle brackets (< >) is expanded somewhere further down in the document. Consider it a high-level PDL (Program Descriptor Language). The trailing number you see within the brackets is where you can find this expansion. It is top-down in appearance, and in actual fact.

6. All the modules follow the same, top-down format. I will group all the boiler-plate into one module, for the compiler, but you will see it with the packages, as they are described.

<Package boiler-plate 7>

7. Getopt Specification.

```

< Package boiler-plate 7 > ≡
  output to file getopt.ads
  with Ustrings;
  use Ustrings;
  with TEXT_IO;
  use TEXT_IO;
  with Ada.Command_Line;
  use Ada.Command_Line;
  package getopt is
    < Specification of types and variables visible from getopt 8 >
    < Specification of procedures visible from getopt 9 >
  end getopt;
  output to file getopt.adb
  < Packages needed by getopt body 11 >
  package body getopt is
    < Variables local to getopt 12 >
    < Procedures and Tasks in getopt 13 >
  end getopt;

```

This code is used in section 6.

8.

```

< Specification of types and variables visible from getopt 8 > ≡
This code is used in section 7.

```

9.

```

< Specification of procedures visible from getopt 9 > ≡
  function option_present(option : in Ustring) return boolean;
  function name_present(Num : natural) return boolean;
  procedure get_option(option : in Ustring; param : out Ustring);
  procedure get_name(name : out Ustring; Num : in natural);

```

This code is used in section 7.

10. GetOpt Body.

11.

⟨ Packages needed by *getopt* body 11 ⟩ ≡
 with *Ada.Strings.Unbounded*; Use *Ada.Strings.Unbounded*; with *Ustrings*;
 use *Ustrings*;

This code is used in section 7.

12.

⟨ Variables local to *getopt* 12 ⟩ ≡
debug : *boolean* ← *false*;

This code is used in section 7.

13.

⟨ Procedures and Tasks in *getopt* 13 ⟩ ≡
 package *natio* is new *integer_io*(*natural*);

See also sections 14, 15, 16, and 19.

This code is used in section 7.

14.

⟨ Procedures and Tasks in *getopt* 13 ⟩ +≡
 function *option_present*(*option* : in *Ustring*) return *boolean* is
 knt : *natural*;
 ispresent : *boolean*;
 begin
 knt ← *Argument_Count*; *ispresent* ← *false*;
 for *i* ∈ 1 .. *knt* loop
 if *S(option)* = *Argument(i)* then
 ispresent ← *true*; exit;
 end if;
 end loop;
 return *ispresent*;
end *option_present*;

15.

⟨ Procedures and Tasks in *getopt* 13 ⟩ +≡

```

procedure get_option(option : in Ustring; param : out Ustring) is
  knt : natural;
begin
  knt ← Argument_Count;
  for i ∈ 1 .. knt loop
    if S(option) = Argument(i) then
      param ← U(Argument(i + 1));
    end if;
  end loop;
end get_option;

```

16.

⟨ Procedures and Tasks in *getopt* 13 ⟩ +≡

```

function name_present(Num : natural) return boolean is
  knt, ic : natural;
  i : natural ← 1;
  fknt : natural ← 0;
  ispresent : boolean;
begin
  ispresent ← false;
  if debug then
    put_line("name_present>");
  end if;
  knt ← Argument_Count;
  while (i ≤ knt) loop
    ⟨ If found option, skip it and its parameter 17 ⟩
    ⟨ if not option, must be name, return true if right number 18 ⟩
  end loop;
  if debug then
    put("Argument_"); natio.put(Num, 1);
    if ispresent then
      put_line("_is_");
    else
      put_line("_is_NOT_");
    end if;
  end if;
  return ispresent;
end name_present;

```

17.

⟨ If found option, skip it and its parameter 17 ⟩ ≡

```

  ic ← Index(U(Argument(i)), "-");
  if ic > 0 then
    i ← i + 2;
  end if;
  if debug then
    put_line("Skipping first option.");
  end if;

```

This code is used in sections 16 and 19.

18.

⟨ if not option, must be name, return *true* if right number 18 ⟩ ≡

```

  if ic = 0 then
    fknt ← fknt + 1;
    if fknt = num then
      if debug then
        put_line("Found your input file name!");
      end if;
      ispresent ← true; exit;
    end if;
    i ← i + 1;
  end if;

```

This code is used in section 16.

19.

⟨ Procedures and Tasks in *getopt* 13 ⟩ +≡

```

  procedure get_name(name : out Ustring; Num : natural) is
    knt, ic : natural;
    i : natural ← 1;
    fknt : natural ← 0;
  begin
    if debug then
      put_line("get_name>");
    end if;
    knt ← Argument_Count;
    while (i ≤ knt) loop
      ⟨ If found option, skip it and its parameter 17 ⟩
      ⟨ if not option, must be name, return if right number 20 ⟩
    end loop;
  end get_name;

```

20.

⟨if not option, must be name, return if right number 20⟩ ≡

```
if ic = 0 then
  fknt ← fknt + 1;
  if fknt = num then
    if debug then
      put_line("Found your input file name!");
    end if;
    name ← U(Argument(i)); exit;
  end if;
  i ← i + 1;
end if;
```

This code is used in section 19.

21. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make MAIN work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

22. RCS Keywords.

```
$RCSfile: getopt.aweb,v
$Revision: 1.1
$Date: 1997/09/05 00:28:36
$Author: evansjr
$Id: getopt.aweb,v 1.1 1997/09/05 00:28:36 evansjr Exp evansjr
$Locker: evansjr
$State: Exp
```

23. Index. Here is a cross-reference table for the MAIN program. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

WEB OUTPUT

APPENDIX H §

This page intentionally left blank

1. Introduction. Here is some code to test capabilities. It is written using Donald Knuth's WEB format for literate programming. To compile and link the code in its present format you will need the Ada version of the WEB tool.

It is available on-line via the world-wide-web at URL:

<http://white.nosc.mil/~evansjr/literate/>

2. WEB is a literate programming paradigm for C, Pascal or Ada, and other languages. This style of programming is called "Literate Programming." For Further information get the book *Literate Programming*, by Donald Knuth, published by the Center for the Study of Language and Information, Stanford University, 1992. Another good source of information is the Usenet group *comp.programming.literate*. It has information on tools and answers to Frequently Asked Questions (FAQs).

3. Who should use the WEB paradigm for programming? Well, not everybody. Here are a few paragraphs from Donald Knuth's book that explains it best.

4. Retrospect and Prospects. Enthusiastic reports about new computer languages, by the authors of those languages, are commonplace. Hence I'm well aware of the fact that my own experiences cannot be extrapolated too far. I also realize that, whenever I have encountered a problem with WEB, I've simply changed the system; other users of WEB cannot operate under the same ground rules.

5. However, I believe that I have stumbled on a way of programming that produces better programs that are more portable and more easily understood and maintained than ever before; furthermore, the system seems to work with large programs as well as with small ones. I'm pleased that my work on typography, which began as an application of computers to another field, has come full circle and become an application of typography to the heart of computer science; I like to think of WEB as a neat "spinoff" of my research on T_EX. However, all of my experiences with this system have been highly colored by my own tastes, and only time will tell if a large number of other people will find WEB to be equally attractive and useful.

6. I made a conscious decision not to design a language that would be suitable for everybody. My goal was to provide a tool for system programmers, not for high school students or for hobbyists. I don't have anything against high school students and hobbyists, but I don't believe every computer language should attempt to offer all things to all people. A user of WEB needs to be good enough at computer science that he or she is comfortable dealing with several languages simultaneously. Since WEB combines TeX and Pascal with a few rules of its own, WEB programs can contain WEB syntax errors. TeX syntax errors, Pascal syntax errors, and algorithmic errors; in practice, all four types of errors occur, and a bit of sophistication is needed to sort out which is which. Computer specialists tend to be better at such things than other people. I have found that WEB programs can be debugged rapidly in spite of the profusion of languages, but I'm sure that many other intelligent people will find such a task difficult.
7. In other words, WEB seems to be specifically for the peculiar breed of people who are called computer scientists. And I'm pretty sure that there are also a lot of computer scientists who will not enjoy using WEB; some of us are glad that traditional programming languages have comparatively primitive capabilities for inserted comments, because such difficulties provide a good excuse for not documenting programs well. Thus, WEB may be only for the subset of computer scientists who like to write and to explain what they are doing. My hope is that the ability to make explanations more natural will cause more programmers to discover the joys of literate programming, because I believe it's quite a pleasure to combine verbal and mathematical skills; but perhaps I'm hoping for too much. The fact that at least one paper has been written that is a syntactically correct ALGOL 68 program encourages me to persevere in my hopes for the future. Perhaps we will even one day find Pulitzer prizes awarded to computer programs.
8. Donald Knuth goes on to write about his hopes for the future of WEB programming. In an interview with Donald Knuth by Amazon Books on the release of a new edition of Volume 1 of *The Art of Computer Programming* (July 1, 1997) he was asked:

Amazon.com: What do you see as the most interesting advance in programming since you published the first edition?

Donald Knuth: It's what I call literate programming, a technique for writing, documenting, and maintaining programs using a high-level language combined with a written language like English. This is discussed in my book *Literate Programming*.

9. In the same book, *Literate Programming*, there is a chapter called *How to read a WEB*. But it is actually quite straightforward.

10. Very briefly, each “Module” within angle brackets (< >) is expanded somewhere further down in the document. The trailing number you see within the brackets is where you can find this expansion. This provides a type of PDL (program descriptor language) for your program and greatly aids modularity and readability. It is also a highly effective method of top-down programming. The first module here is expanded further down, and contains most of the structure in standard Ada packages.

(Package boiler-plate 11)

11. Capabilities specification.

```

<Package boiler-plate 11> ≡
  output to file capability.ads
  with TEXT_IO;
  use TEXT_IO;
  with test_io_pkg;
  use test_io_pkg;

```

80. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make TESTCAP work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

81. RCS Keywords.

```
$RCSfile: capability.aweb,v
$Revision: 1.1
$Date: 1997/09/05 00:31:42
$Author: evansjr
$Id: capability.aweb,v 1.1 1997/09/05 00:31:42 evansjr Exp evansjr
$Locker: evansjr
$State: Exp
```

82. Index. Here is a cross-reference table for the TESTCAP program. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

WEB OUTPUT

APPENDIX I §

This page intentionally left blank

1. Introduction. This routine generates a number of tasks for which a valid schedule exists. The output of this routine is fed into the scheduling algorithm to test its performance. This particular version uses the capability model described in my thesis.

2. This is the main routine that starts everything.

```

output to file task_generator.adb
pragma Unsuppress(all_checks);
with CALENDAR;
use CALENDAR;
with text_io;
use text_io;
⟨ Needed packages 10 ⟩
procedure task_generator is
  package nat_io is new integer_io(natural);
  use nat_io;
  package flt_io is new float_io(float);
  use flt_io;
  package bool_io is new enumeration_io(boolean);
  use bool_io;
  ⟨ Variables local to task_generator 6 ⟩
  ⟨ Functions local to task_generator 33 ⟩
begin
  ⟨ Get input parameters 4 ⟩
  declare
    ⟨ Allocate a static array to hold tasks for schedule 12 ⟩
  begin
    ⟨ Compute earliest available time (EAT) in resource matrix 15 ⟩
    R ← lazily;
    for i ∈ 1 .. tasks loop
      ⟨ Generate another task 16 ⟩
    end loop;
    if do_alterate then
      ⟨ Convert to calendar time 35 ⟩
    end if;
    ⟨ Print out results 34 ⟩
  end;
end task_generator;

```

3. This routine takes two input parameters. (1) “-tasks” the number of tasks to generate; and (2) “-laxity” the laxity, or tightness, parameter. This is formally defined as

$$T_D - T_{est} + T_P$$

where T_D is the deadline, T_{est} is the earliest start-time, and T_P is the processing time. It is computed *apriori* by the *task_generator*.

$$T_D = (1 + R) * SC$$

where R is an input parameter, and SC is the shortest completion time.

4. The input values are read in using the routines in package *getopt*. I read in the number of tasks to compute, the “laxity” of the schedule, and a “seed” for the random number generator.

```

< Get input parameters 4 > ≡
  tasks ← 10;
  if option_present(U("-tasks")) then
    get_option(U("-tasks"), param); get(S(param), tasks, Last);
  end if;
  laxity ← 0.0;
  if option_present(U("-laxity")) then
    get_option(U("-laxity"), param); get(S(param), laxity, Last);
  end if;
  seed ← 68069;
  if option_present(U("-seed")) then
    get_option(U("-seed"), param); get(S(param), seed, Last);
  end if;
  < Get NRaD option 5 >
  < Get developer file 7 >
  < Get developers 8 >

```

This code is used in section 2.

5.

```

< Get NRaD option 5 > ≡
  if option_present(U("-nrad")) then
    get_option(U("-nrad"), param); get(S(param), nrad, Last);
  else
    nrad ← true;
  end if;

```

See also section 45.

This code is used in section 4.

6.

```

⟨ Variables local to task_generator 6 ⟩ ≡
  tasks : natural;
  lazity : float;
  Last : positive;
  param : Ustring;
  seed : natural;
  nrad : boolean;

```

See also sections 9, 13, 18, 19, 22, 26, 29, 30, 32, 37, 41, 44, and 46.

This code is used in section 2.

7.

```

⟨ Get developer file 7 ⟩ ≡
  if name_present(1) then
    get_name(devfile, 1);
  else
    raise nofilename;
  end if;

```

This code is used in section 4.

8.

```

⟨ Get developers 8 ⟩ ≡
  get_developers(S(devfile)); num_developers ← get_num_developers;

```

This code is used in section 4.

9.

```

⟨ Variables local to task_generator 6 ⟩ +≡
  nofilename : exception;
  devfile : ustring;
  num_developers : natural;

```

10. We need some more packages to read in the parameters. Specifically the package *getopt* written by this student; and the package *Ustrings*—used for manipulating “unbounded” strings.

```

⟨ Needed packages 10 ⟩ ≡
  with Ustrings;
  use Ustrings;
  with GetOpt;
  use GetOpt;

```

See also sections 11, 14, 24, and 39.

This code is used in section 2.

11. We also add the following package to enhance the capability model the scheduler (and *task_generator*) can use.

```

⟨ Needed packages 10 ⟩ +≡
  with capability;
  use capability;

```

12.

```

⟨ Allocate a static array to hold tasks for schedule 12 ⟩ ≡
  sched : array (1 .. tasks) of StepRecord;
  newsched : array (1 .. tasks) of NewStepRecord;
  mysample : bool_array (1 .. tasks);

```

See also section 31.

This code is used in section 2.

13.

```

⟨ Variables local to task_generator 6 ⟩ +≡
  type NewStepRecord is
    record
      CalDuration : Duration;
      CalStartTime : Time;
      CalDeadline : Time;
    end record;

```

14.

```

⟨ Needed packages 10 ⟩ +≡
  with generic_set_pkg;
  with SchedPrims;
  use SchedPrims;

```

15.

```

⟨ Compute earliest available time (EAT) in resource matrix 15 ⟩ ≡
  MATRIX_MIN(EAT, Min, COL);

```

This code is used in sections 2 and 28.

16.

```

⟨Generate another task 16⟩ ≡
  ⟨Compute duration of task  $T_p$  17⟩
  ⟨Compute predecessors 25⟩
  ⟨Compute earliest start time 20⟩
  ⟨Compute deadline  $T_D$  21⟩
  ⟨Compute priority  $P$  23⟩
   $sched(i).StepID \leftarrow i$ ;  $sched(i).Deadline \leftarrow T_D$ ;  $sched(i).Priority \leftarrow P$ ;
   $sched(i).EstimatedDuration \leftarrow T_p$ ; ⟨Assign expertise level 27⟩
  ⟨Update resource matrix 28⟩

```

This code is used in section 2.

17. The duration varies in length between MIN_D and MAX_D . The duration will not go over the maximum task deadline (MTD).

```

⟨Compute duration of task  $T_p$  17⟩ ≡
   $T_p \leftarrow uniform(MIN\_D, MAX\_D)$ ; {duration}

```

This code is used in section 16.

18. Minimum task duration.

```

⟨Variables local to task_generator 6⟩ +≡
   $Min\_D : natural \leftarrow 2$ ;

```

19. Maximum task duration.

```

⟨Variables local to task_generator 6⟩ +≡
   $Max\_D : natural \leftarrow 10$ ;

```

20.

```

⟨Compute earliest start time 20⟩ ≡
  for  $j \in 1 \dots (i - 1)$  loop
    if  $nat.set.member(j, sched(i).predecessors)$  then
      if  $Sched(j).deadline > sched(i).EarliestStartTime$  then
         $sched(i).EarliestStartTime \leftarrow Sched(j).Deadline$ ;
        if debug then
          put("Modified  $\square$  Sched. ("); put( $i, 1$ ); put(")  $\square$  to  $\square$  be  $\square$ ");
          put( $sched(i).EarliestStartTime, 1$ ); put_line("  $\square$ ");
        end if;
      end if;
    end if;
  end loop;

```

This code is used in section 16.

21. The deadline (T_D) is a function of the duration and the least value of a resource in the resource matrix.

```

< Compute deadline  $T\_D$  21 >  $\equiv$ 
   $TT \leftarrow \text{integer}(\text{float}(T\_p) * (1.0 + \text{lazity}));$ 
  if debug then
     $\text{put}(\text{"Old\_deadline\_is\_"}); \text{put}(\text{sched}(i).\text{Deadline}, 1); \text{put}(\text{"\_"});$ 
  end if;
  if  $\text{sched}(i).\text{EarliestStartTime} > \text{EAT}(\text{COL})$  then
     $T\_D \leftarrow TT + \text{sched}(i).\text{EarliestStartTime};$ 
  else
     $T\_D \leftarrow TT + \text{EAT}(\text{COL});$ 
  end if;
  if debug then
     $\text{put}(\text{"New\_deadline\_is\_"}); \text{put}(T\_D, 1); \text{put\_line}(\text{"\_"});$ 
  end if;

```

This code is used in section 16.

22.

```

< Variables local to task_generator 6 >  $\equiv$ 
  debug : boolean  $\leftarrow$  false;
  debug2 : boolean  $\leftarrow$  false;

```

23. A random value.

```

< Compute priority  $P$  23 >  $\equiv$ 
   $P \leftarrow \text{uniform}(4, 10);$ 

```

This code is used in section 16.

24.

```

< Needed packages 10 >  $\equiv$ 
  with Probability;
  use Probability;

```

25. I choose to select M out of N tasks as predecessors. M has an upper limit of Max_Predecessors and N is the number of previous tasks assigned. If the number of previous tasks scheduler is less than Max_Predecessors then the minimum is selected then the upper limit is the number of previous tasks scheduled. M is selected randomly.

$\langle \text{Compute predecessors 25} \rangle \equiv$

```

if do_predecessor then
  if  $i \leq \text{Max\_Predecessors}$  then
     $ptasks \leftarrow (i - 1)$ ;
  else
     $ptasks \leftarrow \text{Max\_Predecessors}$ ;
  end if;
   $nsamp \leftarrow \text{uniform}(0, ptasks)$ ;
  if  $i > 1$  then
     $\text{sample}(nsamp, i - 1, \text{mysample})$ ;
    for  $j \in 1 \dots (i - 1)$  loop
      if  $\text{mysample}(j)$  then
         $t1 \leftarrow \text{nat\_set.size}(\text{Sched}(i).\text{Predecessors})$ ;
         $t2 \leftarrow \text{nat\_set.size}(\text{Sched}(j).\text{Successors})$ ;
        if  $(t1 < \text{Max\_Predecessors}) \wedge (t2 < \text{Max\_Predecessors})$  then
           $\text{nat\_set.add}(j, \text{Sched}(i).\text{Predecessors})$ ;  $\text{nat\_set.add}(i, \text{Sched}(j).\text{Successors})$ ;
        end if;
      end if;
    end loop;
  end if;
end if;

```

This code is used in section 16.

26.

$\langle \text{Variables local to task_generator 6} \rangle + \equiv$
 $\text{Max_Predecessors} : \text{constant natural} \leftarrow 0$;
 $ptasks, nsamp : \text{natural}$;
 $t1, t2 : \text{natural}$;

27.

$\langle \text{Assign expertise level 27} \rangle \equiv$

```

declare
   $\text{tmpcap} : \text{cap\_map.map}$ ;
begin
   $\text{copy\_capability}(\text{COL}, \text{sched}(i).\text{ExpLevel})$ ;
end;

```

This code is used in section 16.

28.

```

< Update resource matrix 28 > ≡
  if debug then
    put("Before_Update:"); put("EAT("); put(COL,1); put(")=");
    put(EAT(COL),1); put_line(".");
  end if;
  EAT(COL) ← T_D;
  if debug then

    TotalTime, NRad);

```

This code is used in section 35.

48. System-dependent changes. This module should be replaced, if necessary, by changes to the program that are necessary to make MAIN work at a particular installation. It is usually best to design your change file so that all changes to previous modules preserve the module numbering; then everybody's version will be consistent with the printed program. More extensive changes, which introduce new modules, can be inserted here; then only the index itself will get a new module number.

49. RCS Keywords.

50. Index. Here is a cross-reference table for the MAIN program. All modules in which an identifier is used are listed with that identifier, except that reserved words are indexed only when they appear in format definitions, and the appearances of identifiers in module names are not indexed. Underlined entries of subprograms and packages correspond to sections where this entity is specified, whereas entries in italic type correspond to the section where the entity's body is stated. For any other identifier underlined entries correspond to where the identifier was declared. Error messages and a few other things like "ASCII code" are indexed here too.

INDEX

APPENDIX I §50

Workhours: 46.

Year: 40-41.

Year_number: 41.

- ⟨ Allocate a static array to hold tasks for schedule 12, 31 ⟩ Used in section 2.
- ⟨ Assign expertise level 27 ⟩ Used in section 16.
- ⟨ Compute deadline T_D 21 ⟩ Used in section 16.
- ⟨ Compute duration of task T_p 17 ⟩ Used in section 16.
- ⟨ Compute earliest available time (EAT) in resource matrix 15 ⟩ Used in sections 2 and 28.
- ⟨ Compute earliest start time 20 ⟩ Used in section 16.
- ⟨ Compute predecessors 25 ⟩ Used in section 16.
- ⟨ Compute priority P 23 ⟩ Used in section 16.
- ⟨ Convert Deadline to Calendar Time 47 ⟩ Used in section 35.
- ⟨ Convert Start Time to Calendar Time 43 ⟩ Used in section 35.
- ⟨ Convert Task Duration to Duration type 42 ⟩ Used in section 35.
- ⟨ Convert to calendar time 35 ⟩ Used in section 2.
- ⟨ Find first work-day 38 ⟩ Used in section 36.
- ⟨ Functions local to *task_generator* 33 ⟩ Used in section 2.
- ⟨ Generate another task 16 ⟩ Used in section 2.
- ⟨ Get NRaD option 5, 45 ⟩ Used in section 4.
- ⟨ Get developer file 7 ⟩ Used in section 4.
- ⟨ Get developers 8 ⟩ Used in section 4.
- ⟨ Get input parameters 4 ⟩ Used in section 2.
- ⟨ Get start date 36 ⟩ Used in section 35.
- ⟨ Needed packages 10, 11, 14, 24, 39 ⟩ Used in section 2.
- ⟨ Print out first work day 40 ⟩ Used in section 36.
- ⟨ Print out results 34 ⟩ Used in section 2.
- ⟨ Update resource matrix 28 ⟩ Used in section 16.
- ⟨ Variables local to *task_generator* 6, 9, 13, 18, 19, 22, 26, 29, 30, 32, 37, 41, 44, 46 ⟩
Used in section 2.

INITIAL DISTRIBUTION LIST

1. Defense Technical Information Center 2
 8725 John J. Kingman Road., Ste 0944
 Ft. Belvoir, VA 22060-6218

2. Dudley Knox Library 2
 Naval Postgraduate School
 Monterey, CA 93943

3. Center for Naval Analysis 1
 4401 Ford Ave.
 Alexandria, VA 22302

4. Dr. Ted Lewis, Chairman, Code CS/Lt 1
 Computer Science Dept.
 Naval Postgraduate School
 Monterey, CA 93943

5. Chief of Naval Research 1
 800 North Quincy St.
 Arlington, VA 22217

6. Dr. Luqi, Code CS/Lq 1
 Computer Science Dept.
 Naval Postgraduate School
 Monterey, CA 93943

7. Dr. Marvin Langston 1
 1225 Jefferson Davis Highway
 Crystal Gateway 2 / Suite 1500
 Arlington, VA 22202-4311

8. David Hislop 1
 U.S. Army Research Office
 PO Box 12211
 Research Triangle Park, NC 27709-2211

9. Capt. Talbot Manvel 1
 Naval Sea Systems Command
 2531 Jefferson Davis Hwy.
 Attn: TMS 378 Capt. Manvel
 Arlington, VA 22240-5150

10. CDR Michael McMahon 1
Naval Sea System Command
2531 Jefferson Davis Hwy.
Arlington, VA 22242-5160
11. Elizabeth Wald 1
Office Of Naval Research
800 N. Quincy St.
ONR CODE 311
Arlington , VA 22132-5660
12. Dr. Ralph Wachter 1
Office of Naval Research
800 N. Quincy St.
CODE 311
Arlington, VA 22217-5660
